## INTRODUCTION

This report presents pertinent details associated with Trip 1, 1993. Included in the report are a summary of the trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are then computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 1, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 1, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 1, 1993. Table 4 is a summary of all humpback chubs handled during Trip 1, 1993. Table 5 summarizes the radio contacts during Trip 1, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 260 humpback chub were captured during Trip 1, 1993 including 94 YOY (<101 mm TL), 55 juveniles (100-199 mm TL), and 111 adults (>199 mm TL). All humpback chub were captured in Reach 1 between RM 60 and RM 71. One hundred twenty-seven chubs were captured with seines including 8 adult, 42 juveniles and 77 YOY. Thirty-three chubs, including 11 adults, 11 juveniles and 11 YOY were captured electrofishing. Netting produced 94 humpback chub including 92 adults and 2 juveniles. Six YOY chubs were also captured in unbaited minnow traps.

Over 80% of adult humpback chub handled during Trip 1, 1993 were recaptures. A preliminary analysis of tagging data indicates that approximately 10-15% of these fish were originally marked by BIO/WEST. It is assumed that the remainder of the recaptures were originally marked by AGF or ASU in the LCR. Recapture rates during Trip 1, 1993 represent the highest ever observed by BIO/WEST in the main channel Colorado River, Grand Canyon.

One humpback chub, from which muscle and fin tissues were removed for the Gila taxonomy study was recaptured during Trip 1, 1993. The fish was in good condition and photographs were taken. The fish was originally captured and processed on May 12, 1992, measuring 355 mm TL and weighing 407 g. When recaptured the fish measured 362 mm TL and weighed 563 g. All wounds associated with tissue samples were healed with no signs of infection or other abnormalities.

Five juvenile humpback chubs fin clipped by ASU in the LCR were recaptured by BIO/WEST during Trip 1, 1993. Two fish were marked with upper caudal, right pelvic clips; two fish had upper caudal left pelvic clips; and one had a lower caudal, left pelvic fin clip combination.

## Radiotelemetry

No humpback chubs were implanted with radio transmitters during Trip 1, 1993.

One fish implanted during Trip 9 (September), 1992 was recontacted during one surveillance run during Trip 1, 1993. No observations were conducted during Trip 1, 1993.

Two previously radio-tagged humpback chubs were recaptured during Trip 1, 1993. The first fish was recaptured by electrofishing on January, 15, 432 days after being implanted. The fish was originally captured on November 9, 1991 at RM 60.1, measuring 423 mm TL and weighing 605 g. The fish was recaptured at RM 61.2, measuring 425 mm TL and weighing 658 g. Excluding transmitter weight the fish gained 42 g since it was originally handled. The fish was active and in excellent condition. The primary incision site was completely healed with no sign of infection or other abnormalities. The antenna exit was also in excellent condition with no sign of infection or tissue damage. Fatty-like, epidermal tissue had grown around the antenna exit, extending approximately 2-3 mm up the antenna. Photographs were taken, the antenna was clipped and the fish released.

The second recaptured fish was netted on January 16 at RM 63.75. Attempts to identify the fish from our database led us to discover that the fish was last handled by AGF at RK 0.38 in the LCR on June 3, 1992. At that time AGF personnel recaptured the fish, checked the transmitter, and scanned for a PIT tag. The transmitter was inactive so the antenna was clipped and no PIT tag was detected. A new PIT tag was implanted by AGF and the fish was photographed and released. At the time that AGF handled the fish it measured 394 mm TL and weighed 418 g. The fish was classified as a spent female. When the fish was recaptured by BIO/WEST 175 days later it measured 391 mm TL and weighed 602 g. Since BIO/WEST's original PIT tag was not detected, it is not possible at this time to determine the original capture weight. Attempts will be made to determine the fish's identity from photographs taken by BIO/WEST and AGF. It must be noted that based on timing of captures, field notes on the condition of the fish and weight gain, it is assumed that the fish spawned during 1992 despite the presence of the radiotransmitter.

The omnidirectional remote telemetry station located at RM 60.5 was found inactive on January 11. Despite normal battery outputs the station was not logging and data memory was full of junk data. Initialization parameters and frequency tables were also scrambled. This problem has occurred during three previous trips and is suspected to be associated with static electricity buildup around the station. No data was salvaged from the station for the December and early January period. The station was dismantled and removed from the site.

## Habitat Mapping

GCES surveyors and consultants from Global Hydrographic completed a partial bathymetry survey of the LCR confluence area. Stage information on main channel pooling caused from a high volume flood event out of the LCR was also collected.

## Bench Marks

No new bench marks were established during Trip 1, 1993.

## OBSERVATIONS

1. A large flood emanating from the headwaters of the LCR passed the confluence area during Trip 1, 1993. It is estimated that flows peaked in early afternoon on January 13. Discharge from the LCR was higher than any observed by BIO/WEST during the course of this investigation (since October 1990) and effects on the main channel both above and below the LCR confluence were profound. Water in the main channel appeared to back as far upstream as RM 60.0, with noticeable decreases in water velocity (ponding) and significant stage effects, possibly as much as two vertical feet. Large amounts of sediment deposition occurred from the mouth of the LCR downstream. Significant changes in channel morphology occurred as the result of sediment deposition in these areas.
2. Densities of fish, especially humpback chub were extremely high for approximately 2 to 3 miles below the confluence of the LCR following the flood observed during Trip 1, 1993. Numerous adult, juvenile and YOY chub were captured in low velocity shoreline habitats using electrofishing and seining. Many of the fish appeared to be in relatively poor condition, with numerous abrasions, worn fins and looked gaunt and stressed. It is speculated that a large number of these fish had moved or were flushed from the LCR in response to the flood. This is evidenced by recapture of 5 juvenile humpback chub originally marked by ASU in the LCR and unusually high recapture rates for adults (approximately 80%).
3. Seining and electrofishing catch rates of juvenile and YOY humpback chub were extremely high for 2 to 3 miles below the confluence of the LCR during Trip 1, 1993. Catch rates continually decreased downstream of this point to approximately RM 68 (near Tanner Rapid). Below Tanner Rapid early life stages of humpback chub were rare (2 were captured electrofishing at RM 69.3). It is believed that many of the young humpback chub that disperse into the main channel initially occupy shoreline habitats immediately below the LCR confluence. The distinct geomorphic break that occurs around Lava Canyon (RM 65.5) creates channel morphology with higher gradient providing relatively little protected, slow velocity habitat. Fish that are flushed or disperse into this reach may be forced to continue downstream. With this recent influx of young fish into the main channel, continued main channel sampling effort by BIO/WEST and AGF should provide additional information on dispersal patterns of these fish in the main channel.
4. One large juvenile green sunfish (120 mm TL) was captured at RM 60.1 during Trip 1, 1993. This is only the second individual of this species captured by BIO/WEST during this investigation. It is assumed that this fish entered the main channel via the LCR then dispersed upstream over a mile in the main channel.
5. Two subreaches were sampled in Reach 0 (Lee's Ferry, RM 0.0 to Kwagunt Rapid RM 56.0) during Trip 1, 1993. Sampling was conducted above Soap Creek Rapid and in the Nankowep area. At both sites, catch was dominated by rainbow trout. One flannelmouth sucker captured at Nankowep represented the only native species handled in these two areas. Noteworthy observations on trout in these areas include the capture of a very large brown trout (approximately 9 pounds) in the Nankowep area and an abundance of fingerling trout captured in the Soap Creek area.
6. High densities of Gammurus were observed clinging to debris in nets fished in the Soap Creek area. This phenomena was not observed in nets fished at sites lower in the Canyon.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. During the Trip 1, 1993 BIO/WEST was informed that AGF had recently implaced coded wire nose tags in a significant number of rainbow trout fingerlings that were released between Glen Canyon Dam and Lee's Ferry. Since BIO/WEST has recently expanded its study area to include the reach from Lee's Ferry downstream to Kwagunt Rapid, the probability of BIO/WEST handling some of these fish is very high. Lack of coordination between BIO/WEST and managing agencies precluded BIO/WEST from collecting information on dispersal of these fish downstream of Lee's Ferry. It would seem that understanding dispersal of trout released at Lee's Ferry into the river system would be beneficial to AGF for managing the trout fishery above Lee's Ferry, and to BIO/WEST for expanding our understanding of non-native/native species interactions in the canyon.
2. Inclement weather during Trip 1, 1993 resulted in flooding from numerous tributaries into Marble and Grand Canyons. Frequent rain storms, high turbidities and copious amounts of floating debris (including large trees, > 3 m long) in the main channel affected timing, efficiency and duration of sampling effort to some extent during the trip in all reaches of the study area.
3. Recapture rates of 80% for adult humpback chub suggest the possibility that handling of the population by GCES researchers is excessive. It may be prudent to review research objectives of each entity handling humpback chub in the LCR or Colorado River to determine if the need exists to handle and mark such a large segment of the population. Under current sampling pressure, any proposal for additional handling of the population necessary to achieve specific objectives, should be mitigated by reduced handling associated with other facets of the overall research.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.
2. We recommend that AGF provid BIO/WEST with an electromagnetic detector to identify rainbow trout marked with coded wire tags. Downstream information on dispersal by these fish is valuable for determining the fate of fish released in the tailwaters of Glen Canyon Dam.

## INTRODUCTION

This report presents pertinent details associated with Trip 2, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 2, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 2, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 2, 1993. Table 4 is a summary of all humpback chubs handled during Trip 2, 1993. Table 5 summarizes the radio contacts during Trip 2, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 115 humpback chub were captured during Trip 2, 1993 including 16 YOY (<101 mm TL), 22 juveniles (100-199 mm TL), and 77 adults (>199 mm TL). All but 5 adult humpback chub were captured in Reach 1 between RM 60 and RM 66. In that reach, twelve chubs were captured with seines including 6 juveniles and 6 YOY. Twenty-six chubs, including six adults, 11 juveniles and 9 YOY were captured electrofishing. Netting produced 69 humpback chub including 66 adults and 3 juveniles. Three chubs, one YOY and two juveniles were also captured in unbaited minnow traps.

Five adult humpback chub were captured in Reach 2 between RM 124 and RM 129. All five were captured in nets. Of the five fish, two were recaptures of fish previously tagged in the same locale.

Approximately 75% of adult humpback chub handled during Trip 1, 1993 were recaptures. This represents the second highest recapture rate observed by BIO/WEST in the main channel, second only to an 80% recapture rate observed in January 1993.

One adult humpback chub (approximately 250 mm) was found dead and floating in a large backwater at RM 62.5. Advanced bacterial growth on the surface of the fish indicated that the fish had been dead for some period of time before it was found. No PIT tag or other form of mark was found on the fish. The cause of death was not apparent. Examination of stomach and intestinal contents were inconclusive because gut contents were mostly decayed and unrecognizable. It is speculated that the death of the fish may have been related to recent flood events out of the LCR. The carcass was skeletonized and will be transferred to Rob Clarkson of AGF.

### Radiotelemetry

One humpback chub was implanted with a radio transmitter in Reach 2 during Trip 2, 1993 (Table 5). This was the first humpback chub to be implanted outside of Reach 1. Initiation of telemetry studies in Reach 2 is consistent with 1993 study plans presented to the ACT in December of 1992. Originally it was thought that at least two fish would be needed to conduct a viable telemetry study. This was based on the idea that smaller fish captured in Reach 2 would restrict the size of transmitters to 9 grams with a life expectancy of 50 days. The fish implanted in during Trip 2 weighed 728 grams which allowed the use of an 11 gram transmitter with a life expectancy of 120 days. The life expectancy of the radiotag will allow a greater opportunity to track the fish and implant additional fish in the area while the tag is still active.

An omni-directional remote telemetry station was installed and activated at RM 125.4, the release location of the implanted fish. The station is located in Tapeats ledges approximately 80 feet above river level on river left. Station components included two 20 mm ammunition cans that house two 12 volt gel cell batteries, one receiver and one data logger, one omni-directional whip antenna and a small solar panel. The NPS was notified as to the location of the station on March 2, 1993. BIO/WEST plans to install a second remote station, similar to the one described above during the March Trip. Both remote stations are set up so they can easily be dismantled and moved to locations most suitable for monitoring radiotagged fish utilizing the area. It is anticipated that these stations may be moved to several locations within a river reach extending from approximately RM 124 to RM 129. The NPS will be informed of all activities related to installation of remote telemetry stations in this area.

### Habitat Mapping

No habitat mapping was conducted during Trip 2, 1993. Jack Schmidt (USU) and Ned Andrews (USGS) participated for a portion of the trip measuring sediment deposition from the January flood event from the LCR.

### Bench Marks

No new bench marks were established during Trip 2, 1993.

### **OBSERVATIONS**

1. Unseasonable wet weather during February continued to result in high tributary input during the majority of Trip 2, 1993. High main channel turbidities and excessive floating debris affected sampling efficiency during the trip. Main channel flows were particularly affected late in the trip in response high runoff water in the LCR, similar in magnitude to the flood event out of the LCR in January.
2. High catch rates of humpback chubs in deep eddies above the confluence of the LCR suggest that prespawn staging activities were occurring during Trip 2, 1993.
3. High catch rates of humpback chubs immediately below the confluence of the LCR suggest that a large number of fish are still occupying this area. It is speculated that many of these fish have recently moved out of the LCR in response to unusually high flows. High recapture rate (75%) of PIT tagged fish, the majority of which have been tagged by ASU and AGF lend support to this hypothesis.
4. Approximately 5-10% of the humpback chubs handled during Trip 2, 1993 exhibited tubercles.
5. Moderate numbers of YOY and juvenile humpback chub were captured electrofishing and seining in main channel habitats. Personal observations suggest that densities of these life stages in the main channel are lower than in January. It is speculated that many of the younger humpback chubs had moved into newly created return channel/backwater habitats created during the January flood from the LCR. BIO/WEST did not sample these habitat types during Trip 2, 1993.
6. Five adult humpback chubs were captured in Reach 2 between RM 124 and RM 127. Consistent capture of chubs in this area continues to suggest that an aggregation or small population of fish utilize this area.
7. A majority of rainbow trout captured in Reach 0 were scanned with a metal detector to determine presence of coded wire tags. No tags were detected in any trout captured during Trip 2, 1993.

### **PROBLEMS ENCOUNTERED AND SOLUTIONS**

1. High turbidities and copious floating debris in the main channel affected sampling efficiency. Nets were exchanged more frequently and two netters were used electrofishing when possible to increase efficiency

### **RECOMMENDATIONS**

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.
2. We recommend that AGF continue to provide BIO/WEST with an electromagnetic detector to identify rainbow trout marked with coded wire tags. Downstream information on dispersal by these fish is valuable for determining the fate of fish released in the tailwaters of Glen Canyon Dam.

## INTRODUCTION

This report presents pertinent details associated with Trip 3, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 3, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 3, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 3, 1993. Table 4 is a summary of all humpback chubs handled during Trip 3, 1993. Table 5 presents information on humpback chub implanted with radiotransmitters during Trip 2 and 3, 1993. Table 6 summarizes the radio contacts during Trip 3, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 112 humpback chub were captured during Trip 3, 1993 including 26 YOY (<101 mm TL), 31 juveniles (100-199 mm TL), and 55 adults (>199 mm TL). All but 11 adult humpback chub were captured in Reach 1 between RM 60 and RM 66. In Reach 1, 16 chubs were captured with seines including two adults, nine juveniles and five YOY. Thirty-two chubs, including one adult, 16 juveniles and 15 YOY were captured electrofishing. Netting produced 46 humpback chub including 41 adults and five juveniles. Seven chubs, six YOY and one juvenile were also captured in unbaited minnow traps.

Of the 44 adult humpback chub captured in Reach 1, 30 or 68% were PIT tagged recaptures. No humpbacks bearing Floy or Carlin tags were recaptured during Trip 3, 1993. One YOY humpback chub captured at RM 62.75 was a recaptured fin clipped fish, bearing a ASU fin clip combination of a left pelvic, upper caudal.

Ten adult humpback chub were captured in Reach 2 between RM 126 and RM 128. All ten were captured in nets. Of the ten fish, 6 were recaptures of fish previously tagged in the same locale by BIO/WEST. Three of the recaptures were of fish sampled for the Gila Taxonomy project. The tissue plug scars were completely healed and the fish were in good condition. Two humpback chubs from Reach 2 exhibited tubercles. One chub exhibited spawning coloration.

One adult humpback chub was captured in Reach 0 at RM 29.9. The fish was an unusually large adult, weighing 956 gms and appeared in excellent condition. The fish was not a recapture. This represents the first humpback chub captured by BIO/WEST in Reach 0.

### Radiotelemetry

Two humpback chubs were implanted during Trip 2, 1993 in Reach 2. Both fish were from the Middle Granite Gorge area. One fish was implanted with a 9 gm transmitter and one with an 11 gm transmitter.

The chub implanted in February 1993 was located at the same river mile where released. Radiotelemetry observations were initiated and continued for several days. No major movements were observed.

A second omni-directional remote telemetry station was installed and activated at RM 127.4 left, between release sites of both newly implanted chubs. The other remote station was checked and downloaded during the trip.

### Habitat Mapping

Habitat mapping was conducted at RM 126.1, the location of the February implanted chub.

### Bench Marks

Two new bench marks were established during Trip 3, 1993. One is located on river left at 126.1, and the other river left at RM 127.2.

## OBSERVATIONS

1. Main channel turbidities were high both above and below the LCR during Trip 3, 1993. Consistent runoff from both the Paria and LCR created the turbid conditions. The LCR was flowing relatively high and rising during the trip. It is assumed that rising flows in the LCR are associated with normal spring time runoff from headwater reaches.
2. The capture of numerous gravid and running rainbow trout in and around springs near RM 30 suggest that several of the springs may provide local areas of suitable spawning habitat in the main channel. Temperature of water flowing from the springs measured 15° C, compared to 7-8°C in the main channel.
3. Three rainbow trout were observed in the lower 200 m of Lava Creek during a cursory survey on March 22. BIO/WEST regularly camps at the Lava Creek and has not observed rainbows utilizing the drainage prior to this. It is probable that these fish were engaged in spawning activities. Water temperatures in the creek were ranging from 10 to 12°C and turbidities were low. Although Lava Creek is normally intermittent in character, spring runoff during 1990-92 has been short in duration and low in volume and has, at best, provided marginal spawning habitat for rainbow trout. During 1993 flows have been consistently high since January providing consistent access to the tributary and stable spawning habitat. It is speculated that unusually wet weather during the later part of 1992 and early 1993 may be creating similar conditions in many of the 'normally' intermittent tributaries in the canyon and suitable spawning habitat may be available in areas that are typically not utilized. This being the case, it would not be surprising to observe a strong year class of naturally spawned trout in the Canyon during 1993.
4. Densities of humpback chub, particularly large adults, above the confluence of the LCR were unusually low during Trip 3, 1993. Since fish were observed staging near the LCR in February, low densities were expected at locations removed from the mouth of the LCR. However, in the last two years high numbers of fish have consistently been captured in eddies and runs immediately above the confluence during all months of the year. Low numbers of fish in this area (numbers of flannelmouth sucker were also unusually low) suggest an unusual staging response by both humpback chubs and flannelmouth sucker possibly related to recent flood events from the LCR. It is speculated that fish have either moved en masse into the LCR or are staging in areas other than those observed by BIO/WEST during the last two years.
5. Moderate numbers of adult humpback chub were captured in the main channel in a two mile reach below the LCR confluence. This observation combined with the paucity of adult humpback chub captured above the LCR confluence area suggest that the fish were staging in areas below the LCR, or had already ascended the LCR for spawning.
6. Moderate numbers of juvenile and YOY humpback chubs were captured in shoreline habitat below the confluence of the LCR. Most fish were captured in shoreline habitat provided by large talus and vegetated cutbanks.
7. Significant sediment deposition occurred during the February flood event out of the LCR. Depositional patterns were similar to those observed following the January flood event. Many of the sand bars that were deposited and subsequently eroding after January were rebuilt. More

stable sand bars were similar in size or slightly larger. Deposition resulting from the two LCR floods has significantly altered the channel morphology below the LCR. Most significant changes were incurred in a three mile reach below the confluence. Many eddies and other habitats that existed prior to the flooding have been replaced by massive sand deposits. Significant changes in habitat availability and structure have resulted from the new deposition.

8. Six of the ten chubs caught in Reach 2 were recaptured fish from the same locale as originally captured. This along with previous recapture data from this reach suggest an aggregation or small population of chubs utilizing this area.
9. Three of the ten chubs from Reach 2 exhibited tubercles or spawning coloration.
10. Bright Angel Creek and Havasu Creek were sites of spawning native suckers during Trip 3, 1993. The majority of spawning suckers in Bright Angel Creek were flannelmouths while bluehead suckers dominated in Havasu Creek. One small hoop net set overnight caught over 100 bluehead suckers.

#### **PROBLEMS ENCOUNTERED AND SOLUTIONS**

1. High turbidities in the main channel affected sampling efficiency. Two netters were used electrofishing when possible to increase efficiency.
2. The remote station at RM 126.1 was downloaded by only contained 3 blocks of data. The sensitivity was increased and the station was logging properly when it was left.

#### **RECOMMENDATIONS**

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report presents pertinent details associated with Trip 4, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

### LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 4, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 4, 1993.

### DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 4, 1993. Table 4 is a summary of all humpback chubs handled during Trip 4, 1993. Table 5 presents information on humpback chub implanted with radiotransmitters during Trip 2 and 3, 1993. Table 6 summarizes the radio contacts during Trip 4, 1993 and presents original fish release locations and radiotag data.

#### Humpback Chubs Captured

A total of 143 humpback chub were captured during Trip 4, 1993 including 44 YOY (<101 mm TL), 51 juveniles (100-199 mm TL), and 48 adults (>199 mm TL). In Reach 1, 25 chubs were captured with seines including 11 juveniles and 14 YOY. Forty-three chubs, including three adults, 29 juveniles and 11 YOY were captured electrofishing. Netting produced 30 humpback chub including 27 adults and three juveniles. Twenty-six chubs, 19 YOY and seven juvenile were also captured in unbaited minnow traps.

Four adult humpback chub (3 females and 1 male) were captured in Reach 0 between RM 30.5 - 31.3. All four fish appeared in excellent condition. None of the fish were recaptures. Three of the fish were captured in the same net, in a small eddy about 10 m offshore of a spring. Water at the source of the spring measured 19°C, compared to a mainchannel temperature of 8°C. The water temperature at the approximate point of capture of the three chub was 12°C.

Of the 30 adult humpback chub captured in Reach 1, 18 (or 60%) were PIT-tagged recaptures. No humpbacks bearing Floy or Carlin tags were recaptured during Trip 4, 1993. Three sub-adult humpback chub captured between RM 61.9 - 63.7 were recaptured fin clipped fish, bearing ASU fin clip combinations of left pelvic, lower caudal; right and left pelvic, upper caudal; and right pelvic, upper caudal.

Fifteen humpback chub (13 adults, 2 juveniles) were captured in Reach 2 between RM 126.1 and RM 128.8. Of the 13 adults, seven were recaptures of fish previously tagged in the same locale by

BIO/WEST. Of nine males captured in Reach 2, five were running milt and two others exhibited tubercles.

One juvenile humpback chub (181 mm TL), collected in a trammel net at RM 63.7, was sacrificed for investigation of possible tapeworm infestation. The abdomen of the fish was severely distended and its skin vascularized and discolored; the remainder of the body of the fish appeared emaciated. The described afflictions were not attributable to the sampling gear, nor was the fish a recapture. The fish was dissected in the field, photographed, and preserved, to be turned over to AGF for detailed examination. cursory internal observation revealed unidentified fluid filled sacks on eith side of the ribcage, and a large abnormal tissue mass. No tapeworms were found.

#### Radiotelemetry

No humpback chubs were implanted during Trip 4, 1993.

Both chubs implanted in March 1993 were located at the same river mile where released. Radiotelemetry observations on both fish were initiated and continued for several days. Some significant movement of both fish was observed. The chub implanted in February was not located during this trip, but was logged on the remote station several days prior to our arrival to the area.

Both remote stations were checked and downloaded during the trip. The remote station at RM 127.1 had logged 15,000 blocks of data. The sensitivity was lowered to filter out unusable "noise" and the logger reactivated. The station at RM 126.1 had not logged any data. This station was reprogrammed and initialized to log data.

#### Habitat Mapping

Habitat mapping was conducted at RM 127.1 and 127.5, the location of the March-implanted chubs.

#### Bench Marks

No new bench marks were established during Trip 4, 1993.

## OBSERVATIONS

1. Main channel turbidities were low above the LCR and low to high below the LCR during Trip 4, 1993. The LCR was flowing moderately high but stable during the trip.
2. Gravid and running rainbow trout were collected in and around springs near RM 30, suggesting that several of the springs may provide local areas of suitable spawning habitat in the main channel. Temperature of water flowing from the springs measured as high as 19°C, compared to 8°C in the main channel. Rainbow trout and speckled dace were also observed in Lava Creek (RM 65.5).
3. Flannelmouth suckers were abundant around the mouth of the Paria River (RM 1).
4. Densities of humpback chub, particularly large adults, were low above the confluence of the LCR during Trip 4, 1993. Sampling with nets in and around the mouth of the LCR also captured few chubs. Catch rates were moderate below the LCR to Lava Canyon. This indicates that chubs have ascended the LCR for the 1993 spawning period.
5. One juvenile chub (143 mm TL) was captured by electrofishing above the LCR at RM 60.6.
6. Moderate numbers of juvenile and YOY humpback chubs were captured in shoreline habitat below the confluence of the LCR. Most fish were captured in shoreline habitat provided by large talus and vegetated cutbanks.
7. Two B/W fin-punched juvenile chubs were recaptured in minnow traps. The fish appeared to be in excellent condition, showing no adverse effects due to the mark, although the fish appeared to have been marked during the same trip.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. Fouling of nets with Cladophera probably affected netting sampling efficiency at the first camp, around RM 5. Nets typically had to be replaced after only 2 - 3 hours of fishing. Accumulations of Cladophera, combined with low turbidity levels, probably increased net avoidance by fish.
2. Two outboard motors were running rough midway through the trip. The outboards were switched with spares in the field and will be repaired in the shop before the next trip.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.
2. We recommend a continued radiotelemetry effort in the Middle Granite Gorge to continue to accumulate information on this population through the spawning period and possibly through the remainder of the year.

## INTRODUCTION

This report presents pertinent details associated with Trip 5, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 5, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 5, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 5, 1993. Table 4 is a summary of all humpback chubs handled during Trip 5, 1993. Table 5 presents information on humpback chub implanted with radiotransmitters during Trip 2 and 3, 1993. Table 6 summarizes the radio contacts during Trip 5, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 233 humpback chub were captured during Trip 5, 1993 including 142 juveniles (31-199 mm TL), and 91 adults (>199 mm TL). In Reach 1, 25 juveniles were captured with seines. Forty-one chubs, including two adults, and 39 juveniles were captured electrofishing. Netting produced 84 humpback chub including 68 adults and 16 juveniles. Fifty-seven juvenile chubs were also captured in unbaited minnow traps.

Of the 70 adult humpback chub captured in Reach 1, 46 (or 66%) were PIT-tagged recaptures. One humpback bearing a yellow Floy tag was also recaptured during Trip 5, 1993. Two fin punched sub-adult humpback chub were recaptured between RM 61.9 - 65.4. This represents a 1.4% recapture rate for juvenile chubs (2 of 138). Both fin punches were partially healed indicating that the marks were relatively old, but were distinguishable by the disruption of the fin rays. The fin punched fish were in excellent condition and showed no signs of stress or injury associated with the mark.

One ripe male adult humpback chub was captured in Reach 0 at RM 30.3. The fish appeared in excellent condition and was not a recapture. This fish was captured in the same location as three chubs captured in April, in a small eddy about 10 m offshore of a spring. Water at the source of the spring measured 21.5°C, compared to a mainchannel temperature of 9°C. The water temperature at the approximate point of capture of the three chub was 16°C.

Twenty-three humpback chubs were captured in Reach 2 during Trip 5, 1993 including 20 adults and three juvenile. All adults were captured in nets and the juveniles were captured electrofishing. Of these 20 adult chubs, 6 were recaptures of previously tagged fish. A large number of these fish

exhibited spawning tubercles or expressed milt. Fourteen of these fish were captured between RM 126 and 129.

Two chubs were captured in Reach 3 during Trip 5, 1993. Both were caught in one seine haul at RM 187.6. These chubs were 38 and 58 mm TL.

Stomach contents of 16 humpback chubs, 10 in Reach 1, and 6 in Reach 2, were collected using non-lethal stomach pumping techniques.

### Radiotelemetry

No humpback chubs were implanted during Trip 5 1993.

Two radio-implanted chubs from the Middle Granite Gorge were monitored during Trip 5, 1993. Only localized movements were observed. One implanted chub had moved approximately 0.5 mile downstream since last observed in April 1993.

One radiotagged humpback chub with an active transmitter was recaptured at RM 127.6 during Trip 5. The fish was originally radiotagged on March 19, 1993 and recaptured on May 21, 1993 resulting in an elapsed time of 63 days. Length and weight of the fish when implanted were 386 mm and 874 gm. When recaptured the fish measured 405 mm and weighed 854 (adjusted 11 gms for weight of transmitter), resulting in a weight loss of 20 gms. The fish appeared in excellent condition. Both the main incision and antenna exit were well healed with no signs of infection. One suture was still in place along the main incision and removed. The fish was photographed and released at the capture location.

### Habitat Mapping

Habitat mapping was done in conjunction with 24 hour observations made on two radiotagged humpback chubs between RM 127 and RM 128.

### Bench Marks

Two new bench marks were established in Reach 2 during Trip 5, 1993. One is located on river left at 127.4 and the other is on river right at 127.7.

## OBSERVATIONS

1. Main channel turbidities were low until May 16 when they increased to high in the late morning. Following this time, main channel turbidity stayed high for the remainder of the trip. The LCR ran near base flow and was blue in color between May 10 and May 19. Increases in main channel turbidity were assumed to be the result of storm runoff out of the Paria River.
2. High numbers of spent adult humpback chubs were captured in and around the mouth of the LCR during Trip 5. It is speculated that these fish have spawned in the LCR and are in the process of or staging for migration back into the main channel. In areas away from the mouth of the LCR, catch rates of adult humpback chubs were low.
3. Netting in the main channel in areas away from the LCR confluence area produced higher numbers of adult humpback chub (14 fish) downstream of the confluence area versus the reach above the LCR (1 fish). It is speculated that higher densities of humpback chub below the LCR may be related to two factors: 1) More non-spawning small adults may utilize reaches below the LCR than above and/or; 2) unusual flood events observed in the LCR during January and February may have transported fish from the LCR into the main channel that are still occupying main channel habitats. All adult humpback chubs captured in the main channel during Trip 5 were relatively small adults (<450 gms).
4. Seining main channel habitats during clear water was ineffective for catching juvenile humpback chub. However, when turbidities increased, seining effectiveness increased dramatically. Areas seined during low turbidity were reoccupied during turbid conditions. Under high turbidities humpback chubs were captured in areas where none were captured during low turbidities. Most habitat seined included sand beaches in runs and eddies. This suggests that habitat suitability of these areas was strongly related to cover provided by turbidity.
5. Unbaited minnow traps were very effective at catching juvenile humpback chub during Trip 5. Humpback chubs were captured in a variety of shoreline types including sheer wall, boulder talus, boulder debris fans and vegetated cut banks. High catch rates in minnow traps across habitat types suggest that densities of juvenile humpback chubs were very high in the main channel during Trip 5, 1993.
6. The capture of one large ripe male humpback chub near a spring at RM 30.3 suggests that limited spawning or attempts at spawning may be occurring in the plumes of these springs between RM 29 and RM 30. Capture of 4 humpback chubs (3 females and 1 tubercled male) in the plume of these springs in April support this hypothesis. Water temperatures observed in the spring during Trip 5 were 21.5°C while temperatures of the plumes created by the plume were 16°C.
7. Over 50% of all humpback chubs captured in Reach 2 during Trip 5, 1993 exhibited spawning tubercles or expressed milt.
8. Twenty-four percent of chubs captured in Reach 2 were recaptures of previously PIT-tagged fish.

9. The three recaptured chubs from the Middle Granite Gorge were from the same locale as originally captured. This along with previous recapture data from this site suggest an aggregation or small population of chubs utilizing this area.
10. Kanab and Havasu Creeks were sites of spawning native suckers during Trip 5, 1993. Kanab Creek was dominated by flannelmouths while Havasu Creek was dominated by blueheads.
11. One striped bass was captured at RM 219.9. This fish was a small male with no signs of reproductive condition. The capture of this fish follows the observed trend of spring movements by striped bass seen on previous trips during the past two years.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. High spring flows from Bright Angel and Shinumo Creeks prohibited sampling the inflow areas of these tributaries during Trip 5, 1993. Sampling was performed as near the creek mouths as possible using hoop or trammels nets.
2. The remote telemetry station at RM 127.4 had logged over 5000 blocks of data. All three implanted fish were being logged while field crews only observed two implanted fish during surveillance observations. The sensitivity was adjusted and logging of data continued.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.
2. We recommend a continued radiotelemetry effort in the Middle Granite Gorge to continue to accumulate information on this population through the spawning period and possibly through the remainder of the year.

## INTRODUCTION

This report presents pertinent details associated with Trip 6, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of pertinent trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

### LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 6, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 6, 1993.

### DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 6, 1993. Table 4 is a summary of all humpback chubs handled during Trip 6, 1993. Table 5 presents information on humpback chub implanted with radiotransmitters during Trip 2 and 3, 1993. Table 6 summarizes the radio contacts during Trip 6, 1993 and presents original fish release locations and radiotag data.

#### Humpback Chubs Captured

A total of 120 humpback chub were captured during Trip 6, 1993 including 48 juveniles (41-199 mm TL), and 72 adults (>199 mm TL). In Reach 1, 17 chubs, including 4 adults, and 13 juveniles were captured electrofishing. Netting produced 71 humpback chub including 62 adults and 9 juveniles. Twenty-four juvenile chubs were also captured in unbaited minnow traps.

Of the 65 adult humpback chub captured in Reach 1, 49 were PIT-tagged recaptures. This represents a 75% recapture rate of adult humpback chub in Reach 1 and equals the second highest recapture rate seen during one field trip. BIO/WEST observed a 75% recapture rate in February 1993 and an 80% recapture rate in January 1993. Most of the recaptured fish were marked by other investigators.

Eight humpback chubs were captured in Reach 2 during Trip 5, 1993 including 6 adults and 2 juveniles. Of the six adult humpback chub captured in Reach 2, three were PIT-tagged recaptures of fish originally tagged in Reach 2.

Stomach contents of 10 adult humpback chub in Reach 1 were collected using non-lethal stomach pumping techniques.

#### Radiotelemetry

No humpback chubs were implanted during Trip 6 1993.

One radiotagged humpback chub (PIT Tag No. 7F7D073D4A) was contacted and located a total of eight times during Trip 6, 1993. The fish was moving actively between RM 126.6 and RM 127.6. This fish was recaptured at RM 127.5 on June 19, 1993. The fish was originally radiotagged on March 19, 1993 and recaptured the first time on May 21, 63 days after implant. The fish weighed 854 grams at that time, 20 grams less than when originally captured (874 grams). When recaptured for the second time during Trip 6, 1993, 91 days following implant, the fish weighed 855 grams, or 30 g less than when implanted. The fish appeared in excellent condition at both recaptures. Both the main incision and antenna exit were well healed with no signs of infection. The fish was photographed and released at the capture location.

Both remote stations operating in Reach 2 were functioning normally and downloaded twice during Trip 6, 1993.

#### Habitat Mapping

Juvenile habitat mapping was conducted in 5 locations during Trip 6, 1993. All locations mapped represented areas where juvenile humpback chub were captured during the field trip.

#### Bench Marks

No new bench marks were established during Trip 6, 1993.

## OBSERVATIONS

1. Main channel turbidities were generally low during Trip 6, 1993. Short term increases in turbidity associated with the ascending limb of the hydrograph were observed on most days. However, sediment from tributary sources did not significantly affect main channel turbidities during the trip.
2. LCR turbidities were unusually low during Trip 6, 1993. Visibility through the water in the LCR was approximately 20 feet based on rough estimates made during snorkeling. High water clarity in this system provided an excellent opportunity to conduct direct visual observations of habitat use for all life stages of humpback chubs and other native fish in addition to allowing for an accurate census of predatory species such as channel catfish. Several observations of humpback chub were made by BIO/WEST personnel (B. Masslich) during informal snorkeling in the lower 200 meters of the LCR and are included listed below for those interested (all observations were made on June 12 between 1000 and 1200 hrs):
  - a. One adult humpback chub ( $\approx 300$  mm) was observed utilizing a pool approximately 100 meters upstream of the confluence of the LCR. Maximum depth in the pool was  $\approx 2$  meters. Velocities in the pool ranges from 0 to  $\approx 1$  m/s. The fish was observed moving widely in the pool, utilizing a range of depths and velocities but generally staying in the lower half of the water column. The fish would frequently move into small eddies behind large boulders for brief periods of time. It was highly likely that the activity of the fish was initially influenced by the presence of the observer but seemed to grow accustomed after a period of time, at one point passing within one meter of the observer. During the observation the fish used an area of  $\approx 100$  square meters before moving upstream out of sight. Total observation time was about 2 minutes.
  - b. One juvenile humpback chub ( $\approx 120$  mm) was observed utilizing a small eddy created by an imbedded boulder on the bottom. Water depth at the fishes location was  $\approx 1.5$  m and water velocity  $\approx -0.1$  m/s. The fish was observed at this location for approximately 30 seconds before it moved upstream, possibly flushed by presence of the observer.
  - c. Three young-of-year humpback chub were observed utilizing the interstitial space between two large boulders approximately 75 meters up the LCR from the confluence. The fish ranged from  $\approx 20$ -25 mm TL. The area utilized by the fish was approximately 0.5 square meters. Water velocity in the area used by the fish ranged from 0.0 to near 0.5 m/s. The fish were observed spending most of the time in calm water but occasionally moved near the shear zone of the small eddy created by a  $\approx 1.0$  m/s current flowing past their location. Several times the fish appeared to get caught in the current passing their location and had to swim very vigorously to return back to the space between the boulders. During the observation the fish were feeding on drifting material as well as foraging off the surface of boulders. Items eaten by the fish could not be identified. Water depth at the fishes location was  $\approx 0.25$  m. Total observation time was about 4 minutes.
  - d. A snorkeling census was made of the lower intermittent channel at the confluence of the LCR. At the time of the survey main channel flows were low and no water was flowing through the lower channel. A pool approximately 40 meters long and 5 meters wide was examined to determine numbers of small humpback chub that were utilizing the area. Maximum depth in the

pool was  $\approx 1$  m. Approximately 10 unidentified larval fish were observed utilizing a very shallow, warm area at the top end of the pool. One large channel catfish ( $\approx 7$  lb.) was observed under Tapeats ledges near the middle of the pool. Approximately 30-40 small fish, mostly speckled dace (no chubs were positively identified) were packed into a small scoured area under a Tapeats ledge at the base of the pool. As the observer moved down the pool careful it did not appear that any fish were being pushed. It is speculated that this group of young fish were utilizing this portion of the pool in response to the large catfish that was resting approximately 2 meters from their location. Based on the limited area and cover available in the pool it is speculated that predation of young fish was a limiting factor in the pool at the time of the observation. No attempts were made to capture the catfish for stomach analysis.

3. Twenty-one rainbow trout were captured netting and electrofishing above the confluence of the LCR during Trip 6 versus 7 rainbows captured below the confluence of the LCR. It is speculated that prolonged turbidity from the LCR during the last year may have resulted in emigration of rainbow trout from areas below the confluence of the LCR. Assuming this is the case, levels of predation on young native fish using this reach may be reduced temporarily. It is unknown the time it will take for immigration of trout back into the area under conditions of low turbidity as observed during Trip 6.
4. A juvenile humpback chub ( $\approx 110$  mm) was observed in Chuar Creek during Trip 6, 1993. The fish was observed at 1300 on June 16 while observing a school of speckled dace in a small artificial pool 10 m upstream of the confluence of Chuar Creek and the Colorado River. The pool was created by a small handmade boulder dam measured approximately 5 meters in length with a maximum depth of 0.3 meters. While watching dace swimming in the pool, the young chub swam into the pool from upstream. A second person was called over to see the fish. At this time the fish became very flighty, darting around in the pool and eventually came out of the water, flopped over the small dam and swam downstream toward the confluence at which time visual contact with the fish was lost. It is speculated that the fish had probably moved into the creek earlier in the year when flows in the creek were relatively high ( $>1$  cfs) and warmer than the main channel. Flow in Chuar creek at the time of the observation was  $\approx 0.25$  cfs.
5. Four juvenile humpback chub (100-120 mm) were observed feeding at the break of an eddy at RM 65.4 on June 17 at approximately 2300 hr. The fish were utilizing water depths ranging from 0.5 to 1.5 feet approximately 1 to 3 feet from shore. Water velocities at the fishes location ranged from 0.1 to 0.3 m/s over a sand substrate. The fish were observed orienting themselves into the current at the break of the eddy and feeding on material drifting into the eddy and settling out. Total observation time was approximately 30 minutes. It is speculated that these fish moved out of the cover of a vegetated shoreline just downstream of the eddy to feed during the night in clear water then returned to the cover during the day. Several humpback chub in the same size range were captured along this vegetated bank in unbaited minnow traps. It had been speculated by BIO/WEST that juvenile humpback chubs were utilizing these areas as feeding sites during the day during high turbidity (see Trip Report #8 and #9, 1992). This observation indicates that these areas may also be important feeding sites during night in low turbidity situations.

6. High catch rates of adult humpback chubs between 60 mile Rapid and Chuar Creek suggest that a substantial number of humpback chubs have migrated back into the main channel from the LCR following spawning. A large proportion of the fish appeared relatively flaccid and spent.
7. A female striped bass (539 mm TL, 1928 g) was captured angling from the mouth of Kanab Creek. This fish was captured using a spin casting rod with a fluorescent 1/4 oz "Crocodile" spoon
8. Three striped bass were captured by electrofishing in the mouth of Havasu Creek. Several unidentified suckers were noted in the stomach of one fish (complete identification of stomach contents has not yet been completed)

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. No substantial problems were encountered in Trip 6, 1993.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.
2. We recommend that radiotelemetry efforts in the Middle Granite Gorge be discontinued after July 1993. BIO/WEST has had the opportunity to monitor three radiotagged fish in the area since March of 1993 and has collected adequate information to address objectives of the telemetry study in Reach 2. Further telemetry studies would require intensive effort in the area and result in little additional information.

## INTRODUCTION

This report presents pertinent details associated with Trip 7, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 7, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 7, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 7, 1993. Table 4 is a summary of all humpback chubs handled during Trip 7, 1993. Table 5 summarizes the radio contacts during Trip 7, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 431 humpback chub were captured during Trip 7, 1993 including 247 young-of-year (YOY) (<65 mm), 90 juveniles (66-199 mm TL), and 94 adults (>199 mm TL). No chub were captured in Reach 0. In Reach 1, a total of 409 humpback chubs were captured including 246 YOY, 85 juveniles and 78 adults. Forty YOY were captured with seines. One hundred eighty-seven chubs, including 15 adults, 58 juveniles and 114 YOY were captured electrofishing. Netting produced 66 humpback chub including 63 adults and 3 juveniles. One hundred sixteen chubs were also captured in unbaited minnow traps including 24 juveniles and 92 YOY.

Of the 78 adult humpback chub captured in Reach 1, 60 (or 77%) were PIT-tagged recaptures (includes those captured and marked by other investigators). This represents the second highest recapture rate observed by BIO/WEST for adult humpback chubs in Reach 1. Other high recapture rates were observed in 1993, including 80% in January, 75% in February, 68% in March, 60% in April, 66% in May and 75% in June.

Twenty-two humpback chubs were captured in Reach 2 during Trip 7, 1993 including 16 adults and five juveniles and one YOY. Fifteen adults and 1 juvenile were captured in nets. One adult and two juveniles were captured electrofishing and one YOY and 2 juveniles were captured in unbaited minnow traps. Of these 17 adult chubs, 7 were recaptures of previously tagged fish. All were captured near their original capture location. Seventeen of these fish were captured between RM 126 and 128. No chubs were captured in Reach 3.

Stomach contents of 20 humpback chubs, 15 in Reach 1 and 5 in Reach 2, were collected using non-lethal stomach pumping techniques.

One YOY humpback chub captured electrofishing at RM 75.1 on July 13 was discovered dead in the live well at the end of the electrofishing run. The fish was missing an eye and based on its overall appearance was assumed to be either dead or in very poor condition prior to capture. The fish measured 64 mm TL and weighed 2 grams. The carcass was preserved for transport to Flagstaff and will be transferred to AGF as soon as possible.

#### Observed Condition of Humpback Chub

All chubs captured with the exception of one juvenile captured at RM 68.3 appeared healthy and in good condition. The juvenile captured at RM 68.3 had a distended abdomen and appeared slightly malnourished, possibly as a result of a tapeworm infestation. The fish was released at the point of capture.

Non-lethal stomach pumping of 15 humpback chubs indicated that tapeworms were present in approximately 33% of the fish that were successfully evacuated.

#### Radiotelemetry

No humpback chubs were implanted during Trip 7 1993.

One radio-implanted chub from the Middle Granite Gorge was located by radiotelemetry during Trip 7, 1993. The fish (40.730) was located during a routine surveillance run on July 16 at RM 126.2. This was the only contact with the fish during the four days of telemetry surveillance. It is assumed that the transmitter expired.

Both remote telemetry stations were downloaded successfully during Trip 7, 1993. These data show upstream movement by 40.730 about one week prior to arrival of the B/W crew to the Middle Granite Gorge area this month.

#### Habitat Mapping

Juvenile habitat mapping was conducted in seventeen locations between the confluence of the LCR and Tanner Rapid.

#### Bench Marks

No new bench marks were established during Trip 7, 1993.

## OBSERVATIONS

1. Main channel turbidities were low for the duration of Trip 7, 1993. Daily increases in fluctuations in turbidity associated with bed load disturbance from peak flows were observed during most days. Turbidities ranged from 7 to 35 NTU's during a flow cycle, with highest turbidities observed during the descending limb of the hydrograph soon after peak flow.
2. High densities of YOY humpback chub were observed in the main channel from the confluence of the LCR (RM 61.3) to Nevill's Rapid (RM 75.3) during Trip 7, 1993. YOY humpback were captured in nearly all shoreline types by electrofishing, seining and minnow trapping. Highest catch rates were along shoreline types including talus, debris flows and vegetated cutbanks. Shoreline types such as sand beaches and shear walls yielded lower catch rates. Based on observations of movement and transport of YOY and juvenile chub from the LCR into the main channel during previous years, the presence of such high numbers of YOY humpback chub in the main channel during Trip 7 is anomalous. During previous years dramatic increases in numbers of YOY and juvenile humpback chub in the main channel were generally associated with a flood event in the LCR. No such event has occurred in the LCR following the spring runoff which ended in late April-early May. Since that time the LCR has run at base flow. It is speculated that movement of these young fish may be associated with one or a combination of the following factors:
  - a) Flood events during January and February of 1993 scoured the LCR channel possibly increasing availability of suitable spawning habitat for humpback chub and resulted in an exceptionally successful spawn. Unusually high numbers of YOY chubs in the main channel may be reflective of normal emigration associated with very high densities of fish in the LCR.
  - b) Scouring of the LCR by unusually high winter and early spring flows appear to have resulted in unusually high water clarity in the LCR during June and July. It is possible that high water clarity in the LCR may be unsuitable for YOY humpback chub resulting in emigration into the main channel.
  - c) Scouring of the LCR as described above may have temporarily altered benthic and planktonic communities resulting in decreased food availability for high numbers of YOY fish in the system again resulting in emigration into the main channel.
3. Water clarity in the LCR was unusually high in July. Numerous YOY humpback chubs (ranging from approximately 30 to 60 mm) were observed while snorkeling in the lower one kilometer. Several juvenile and one adult humpback chub were also observed and photographed. Numerous channel catfish and carp were also observed and photographed.
4. Two brown trout were captured in Reach 1 during Trip 7, 1993, one at RM 62.1 and one at 68.4. Both browns were captured in conjunction with high numbers of YOY and juvenile humpback chub and were sacrificed for stomach content analysis. A total of 6 humpback chubs were found in the stomach contents of both fish (2 in one fish and 4 in the other) averaging 94 mm standard length, with a range of 78-120 mm. A total length of 162 mm was measured for one of the chubs that was freshly ingested.

5. All rainbow trout captured in conjunction with YOY humpback chub were sacrificed for stomach analysis. Fish remains were tentatively identified in the stomach of three of these fish and preserved for lab identification.
6. Unbaited minnow traps were very effective at catching YOY and juvenile humpback chub during Trip 7. Humpback chubs were captured in a variety of shoreline types including sheer wall, boulder talus, boulder debris fans and vegetated cut banks. High catch rates in minnow traps across habitat types suggest that densities of both YOY and juvenile humpback chubs were very high in the main channel during Trip 7, 1993.
7. Two small chub, 76 and 68 mm TL were captured in minnow traps at RM 126.1. This is the first collection of chub this small from the Middle Granite Gorge area.
8. Thirty-two percent of chubs captured in Reach 2 were recaptures of previously PIT tagged fish.
9. The seven recaptured chubs from the Middle Granite Gorge were from the same locale as originally captured. This along with previous recapture data from this site suggest an aggregation or small population of chubs utilizing this area.
10. Mainstem river warming was apparent during Trip 7, 1993. River temperatures were 14.5 °C at RM 143 and 16.5 °C at RM 214.
11. Fifteen striped bass were captured during Trip 7, 1993. Six were caught in nets above Kanab Creek in Reach 2. In Reach 3, 9 bass were captured by both electrofishing and netting. Sites below Havasu Creek and at RM 214 produced striped bass. These fish were mostly non-reproductive males between 1 and 2 pounds. The capture of these fish follows the observed trend of summer movements by striped bass seen on previous trips during the past two years.

## **PROBLEMS ENCOUNTERED AND SOLUTIONS**

1. One PIT tagger was malfunctioning during Trip 7, 1993. some sampling efficiency was lost by having shuttle fish to be PIT tagged. this instrument will be serviced as soon as possible.

## **RECOMMENDATIONS**

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report presents pertinent details associated with Trip 7, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 7, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 7, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 7, 1993. Table 4 is a summary of all humpback chubs handled during Trip 7, 1993. Table 5 summarizes the radio contacts during Trip 7, 1993 and presents original fish release locations and radiotag data.

### Humpback Chubs Captured

A total of 431 humpback chub were captured during Trip 7, 1993 including 247 young-of-year (YOY) (<65 mm), 90 juveniles (66-199 mm TL), and 94 adults (>199 mm TL). No chub were captured in Reach 0. In Reach 1, a total of 409 humpback chubs were captured including 246 YOY, 85 juveniles and 78 adults. Forty YOY were captured with seines. One hundred eighty-seven chubs, including 15 adults, 58 juveniles and 114 YOY were captured electrofishing. Netting produced 66 humpback chub including 63 adults and 3 juveniles. One hundred sixteen chubs were also captured in unbaited minnow traps including 24 juveniles and 92 YOY.

Of the 78 adult humpback chub captured in Reach 1, 60 (or 77%) were PIT-tagged recaptures (includes those captured and marked by other investigators). This represents the second highest recapture rate observed by BIO/WEST for adult humpback chubs in Reach 1. Other high recapture rates were observed in 1993, including 80% in January, 75% in February, 68% in March, 60% in April, 66% in May and 75% in June.

Twenty-two humpback chubs were captured in Reach 2 during Trip 7, 1993 including 16 adults and five juveniles and one YOY. Fifteen adults and 1 juvenile were captured in nets. One adult and two juveniles were captured electrofishing and one YOY and 2 juveniles were captured in unbaited minnow traps. Of these 17 adult chubs, 7 were recaptures of previously tagged fish. All were captured near their original capture location. Seventeen of these fish were captured between RM 126 and 128. No chubs were captured in Reach 3.

Stomach contents of 20 humpback chubs, 15 in Reach 1 and 5 in Reach 2, were collected using non-lethal stomach pumping techniques.

One YOY humpback chub captured electrofishing at RM 75.1 on July 13 was discovered dead in the live well at the end of the electrofishing run. The fish was missing an eye and based on its overall appearance was assumed to be either dead or in very poor condition prior to capture. The fish measured 64 mm TL and weighed 2 grams. The carcass was preserved for transport to Flagstaff and will be transferred to AGF as soon as possible.

#### Observed Condition of Humpback Chub

All chubs captured with the exception of one juvenile captured at RM 68.3 appeared healthy and in good condition. The juvenile captured at RM 68.3 had a distended abdomen and appeared slightly malnourished, possibly as a result of a tapeworm infestation. The fish was released at the point of capture.

Non-lethal stomach pumping of 15 humpback chubs indicated that tapeworms were present in approximately 33% of the fish that were successfully evacuated.

#### Radiotelemetry

No humpback chubs were implanted during Trip 7 1993.

One radio-implanted chub from the Middle Granite Gorge was located by radiotelemetry during Trip 7, 1993. The fish (40.730) was located during a routine surveillance run on July 16 at RM 126.2. This was the only contact with the fish during the four days of telemetry surveillance. It is assumed that the transmitter expired.

Both remote telemetry stations were downloaded successfully during Trip 7, 1993. These data show upstream movement by 40.730 about one week prior to arrival of the B/W crew to the Middle Granite Gorge area this month.

#### Habitat Mapping

Juvenile habitat mapping was conducted in seventeen locations between the confluence of the LCR and Tanner Rapid.

#### Bench Marks

No new bench marks were established during Trip 7, 1993.

## OBSERVATIONS

1. Main channel turbidities were low for the duration of Trip 7, 1993. Daily increases in fluctuations in turbidity associated with bed load disturbance from peak flows were observed during most days. Turbidities ranged from 7 to 35 NTU's during a flow cycle, with highest turbidities observed during the descending limb of the hydrograph soon after peak flow.
2. High densities of YOY humpback chub were observed in the main channel from the confluence of the LCR (RM 61.3) to Nevill's Rapid (RM 75.3) during Trip 7, 1993. YOY humpback were captured in nearly all shoreline types by electrofishing, seining and minnow trapping. Highest catch rates were along shoreline types including talus, debris flows and vegetated cutbanks. Shoreline types such as sand beaches and shear walls yielded lower catch rates. Based on observations of movement and transport of YOY and juvenile chub from the LCR into the main channel during previous years, the presence of such high numbers of YOY humpback chub in the main channel during Trip 7 is anomalous. During previous years dramatic increases in numbers of YOY and juvenile humpback chub in the main channel were generally associated with a flood event in the LCR. No such event has occurred in the LCR following the spring runoff which ended in late April-early May. Since that time the LCR has run at base flow. It is speculated that movement of these young fish may be associated with one or a combination of the following factors:
  - a) Flood events during January and February of 1993 scoured the LCR channel possibly increasing availability of suitable spawning habitat for humpback chub and resulted in an exceptionally successful spawn. Unusually high numbers of YOY chubs in the main channel may be reflective of normal emigration associated with very high densities of fish in the LCR.
  - b) Scouring of the LCR by unusually high winter and early spring flows appear to have resulted in unusually high water clarity in the LCR during June and July. It is possible that high water clarity in the LCR may be unsuitable for YOY humpback chub resulting in emigration into the main channel.
  - c) Scouring of the LCR as described above may have temporarily altered benthic and planktonic communities resulting in decreased food availability for high numbers of YOY fish in the system again resulting in emigration into the main channel.
3. Water clarity in the LCR was unusually high in July. Numerous YOY humpback chubs (ranging from approximately 30 to 60 mm) were observed while snorkeling in the lower one kilometer. Several juvenile and one adult humpback chub were also observed and photographed. Numerous channel catfish and carp were also observed and photographed.
4. Two brown trout were captured in Reach 1 during Trip 7, 1993, one at RM 62.1 and one at 68.4. Both browns were captured in conjunction with high numbers of YOY and juvenile humpback chub and were sacrificed for stomach content analysis. A total of 6 humpback chubs were found in the stomach contents of both fish (2 in one fish and 4 in the other) averaging 94 mm standard length, with a range of 78-120 mm. A total length of 162 mm was measured for one of the chubs that was freshly ingested.

5. All rainbow trout captured in conjunction with YOY humpback chub were sacrificed for stomach analysis. Fish remains were tentatively identified in the stomach of three of these fish and preserved for lab identification.
6. Unbaited minnow traps were very effective at catching YOY and juvenile humpback chub during Trip 7. Humpback chubs were captured in a variety of shoreline types including sheer wall, boulder talus, boulder debris fans and vegetated cut banks. High catch rates in minnow traps across habitat types suggest that densities of both YOY and juvenile humpback chubs were very high in the main channel during Trip 7, 1993.
7. Two small chub, 76 and 68 mm TL were captured in minnow traps at RM 126.1. This is the first collection of chub this small from the Middle Granite Gorge area.
8. Thirty-two percent of chubs captured in Reach 2 were recaptures of previously PIT tagged fish.
9. The seven recaptured chubs from the Middle Granite Gorge were from the same locale as originally captured. This along with previous recapture data from this site suggest an aggregation or small population of chubs utilizing this area.
10. Mainstem river warming was apparent during Trip 7, 1993. River temperatures were 14.5 °C at RM 143 and 16.5 °C at RM 214.
11. Fifteen striped bass were captured during Trip 7, 1993. Six were caught in nets above Kanab Creek in Reach 2. In Reach 3, 9 bass were captured by both electrofishing and netting. Sites below Havasu Creek and at RM 214 produced striped bass. These fish were mostly non-reproductive males between 1 and 2 pounds. The capture of these fish follows the observed trend of summer movements by striped bass seen on previous trips during the past two years.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. One PIT tagger was malfunctioning during Trip 7, 1993. some sampling efficiency was lost by having shuttle fish to be PIT tagged. this instrument will be serviced as soon as possible.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report presents pertinent details associated with Trip 8, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 8, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 8, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 8, 1993. Table 4 is a summary of all humpback chubs handled during Trip 8, 1993.

### Humpback Chubs Captured

A total of 730 humpback chub were captured in Reach 1 during Trip 8, 1993 including 581 young-of-year (YOY) (<60 mm), 109 juveniles (60-199 mm TL), and 40 adults (>199 mm TL). No chub were captured in Reach 0. Fifty-one juvenile and 190 YOY were captured with seines. Three hundred and fifty-nine chubs, including 3 adults, 32 juveniles and 324 YOY were captured electrofishing. Netting produced 37 adult humpback chub and 1 juvenile. Ninety-two chubs were also captured in unbaited minnow traps including 25 juveniles and 67 YOY.

Of the 40 adult humpback chub captured in Reach 1, 35 (or 85%) were PIT-tagged recaptures (includes those captured and marked by other investigators). This represents the highest recapture rate observed by BIO/WEST for adult humpback chubs in Reach 1. Other high recapture rates were observed in 1993, including 80% in January, 75% in February, 75% in June and 77% in July.

Stomach contents of 21 humpback chubs were collected in Reach 1 using non-lethal stomach pumping techniques.

One YOY humpback chub was found dead in a minnow trap at RM 63.9 on August 18. The fish measured 58 mm TL. The carcass was preserved for transfer to AGF.

### Observed Condition of Humpback Chub

All chubs captured, with the exception of one juvenile appeared healthy and in good condition. The juvenile, captured at RM 62.15, had a white discoloring along the caudal peduncle and appeared weak and in poor condition. The chub was not a recapture and not pit-tagged due to its condition. The fish was released at the point of capture.

Non-lethal stomach pumping of 21 humpback chubs indicated that tapeworms were present in approximately 25% of the fish that were successfully evacuated.

### Habitat Mapping

Juvenile habitat mapping was conducted in twelve locations between the confluence of the LCR and Tanner Rapid.

### Bench Marks

One temporary bench mark was established at Tanner Canyon. The benchmark was placed in the ledges on the left side at RM 68.25.

## OBSERVATIONS

1. Runoff from the Paria River created high main channel turbidity until August 16. Mainchannel turbidity was low from August 16 - 19. Heavy rains caused high main channel turbidity at approximately 4:00 pm on August 19. Turbidity was high for the remainder of Trip 8, 1993.
2. Heavy rains caused a flash flood in Tanner Canyon at 4:30 pm on August 19. The flood created a large debris fan just above Tanner Rapid, which noticeably decreased water velocity and increased river stage approximately one vertical foot for 0.4 miles upstream.
3. High densities of YOY humpback chub were observed in the main channel from the confluence of the LCR (RM 61.3) to Hance Rapid (RM 76.5) during Trip 8, 1993. YOY humpback were captured in nearly all shoreline types by electrofishing, seining and minnow trapping.
4. Water clarity in the LCR was high in August. Numerous YOY humpback chubs (ranging from approximately 40 to 60 mm TL) were observed while snorkeling in the lower one kilometer.
5. All rainbow trout captured in conjunction with YOY humpback chub were sacrificed for stomach analysis.
6. A juvenile night heron was observed feeding on several small fish in a backwater just above Unkar Rapid (RM 72.3, left side). Seining in the area revealed large numbers of YOY humpback chub.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. One outboard motor would not shift into reverse. This motor was repaired by changing the lower-unit, the old gearbox will be serviced as soon as possible.

## RECOMMENDATIONS

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report presents pertinent details associated with Trip 9, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 9, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 9, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 9, 1993. Table 4 is a list of all humpback chubs marked or recaptured during Trip 9, 1993.

### Humpback Chubs Captured

A total of 1,141 humpback chub were captured during Trip 9, 1993 including 769 young-of-year (YOY) (<65 mm), 286 juveniles (66-199 mm TL), and 86 adults (>199 mm TL). Nine adult chub were captured in Reach 0, seven by netting and two by electrofishing. In Reach 1, a total of 1066 humpback chubs were captured including 737 YOY, 275 juveniles and 54 adults. A total of 520 humpback chubs including 310 YOY, 209 juveniles and one adult were captured with seines. Three hundred seventy six chubs, including 5 adults, 30 juveniles and 341 YOY were captured electrofishing. Netting produced 48 adult humpback chub. One hundred and twenty two chubs were also captured in unbaited minnow traps including 36 juveniles and 86 YOY.

Of the 54 adult humpback chub captured in Reach 1, 42 (or 78%) were PIT-tagged recaptures (includes those captured and marked by other investigators). In Reach 0, one of seven adult humpback chubs were recaptures. The recaptured fish in Reach 0 was a fish tagged in the same area (near Fence Fault) in May of 1993.

Sixty-six chub were caught in Reach 2. Thirty-five were YOY, 11 were juvenile and 20 were adults. Every gear type caught chub. YOY chub were caught seining intermittently in the Inner Gorge to Bright Angel Creek. Fewer were captured downstream. Most of the adult chub came from the Middle Granite gorge. Recaptures from this area were about 30-40 percent.

One adult chub was recaptured at RM 108.5 during Trip 9, 1993 that was originally tagged in July 1992 at RM 127.5. This fish had grown in both weight and length and was in good condition. This upstream movement of about 20 miles is the longest upstream movement by humpback chub during this study.

Stomach contents of 21 humpback chubs, 15 in Reach 1 and 6 in Reach 2, were collected using non-lethal stomach pumping techniques.

Two YOY humpback chub captured in a minnow trap at RM 63.9 on September 18 were discovered dead in the trap during a routine check. The fish measured 80 and 61 mm TL. The carcasses were preserved for transport to Flagstaff and will be transferred to AGF as soon as possible.

#### Observed Condition of Humpback Chub

All chubs captured appeared healthy and in good condition with the exception of a small percentage of both juvenile and YOY chubs captured at various locations which again exhibited a slight swelling of the abdominal area and appeared slightly gaunt, possibly as a result of tape worm infestation. This abdominal swelling has been noticed in some individuals during most trips, but generally affects much less than 1% of the fish captured.

#### Radiotelemetry

Both remote stations from the Middle Granite Gorge were decommissioned during Trip 9, 1993. All equipment was removed from the sites and no tract of their existence was left behind. No humpback chubs were implanted during Trip 9 1993.

#### Habitat Mapping

Juvenile habitat mapping was conducted in fifteen locations between the confluence of the LCR and Tanner Rapid.

#### Bench Marks

No new bench marks were established during Trip 9, 1993.

## OBSERVATIONS

1. Main channel turbidities above the LCR were low for the duration of Trip 9, 1993. Daily increases in fluctuations in turbidity associated with bed load disturbance from peak flows were observed during most days. Turbidities were high below the confluence of the LCR for the duration of Trip 9, 1993.
2. High densities of YOY humpback chub were observed in the main channel from the confluence of the LCR (RM 61.3) to Hance Rapid (RM 78.4) during Trip 9, 1993. YOY humpback were captured in nearly all shoreline types by electrofishing, seining and minnow trapping. Highest catch rates were along shoreline types including talus, debris flows and vegetated cutbanks.
3. One rainbow trout captured seining along with numerous YOY humpback chubs was sacrificed for stomach analysis. Observations of stomach contents in the field indicated that the carcasses of at least three small fish were among the food items. Stomach contents were preserved for lab identification.
4. Unbaited minnow traps were very effective at catching YOY and juvenile humpback chub during Trip 9 despite high turbidities. Humpback chubs were captured in a variety of shoreline types including sheer wall, boulder talus, boulder debris fans and vegetated cut banks. High catch rates in minnow traps across habitat types and under turbid conditions strongly suggest that densities of both YOY (40 mm - 60 mm) and juvenile humpback chubs were very high in the main channel during Trip 9, 1993.
5. The majority of adult fish captured by the lower crew during Trip 9, 1993 were from the Middle Granite Gorge. The consistent high recapture success indicates an affinity for this area by this aggregation of chub.
6. No striped bass were captured during Trip 9, 1993. The high turbidity and cooler water temperatures this month may be a factor in this observation.
7. One 25 mm TL green sunfish was caught electrofishing at RM 173.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. The addition of one research boat by GCES for the purposes of surveying created some minor difficulties during Trip 9, 1993. We recommend that if additional research boats are going to be added to the manifest of a trip, a boatman should accompany the boat or arrangements should be made for the safe transport of the boat to the takeout. The boat was transported, rolled and loaded on a 37' support raft.
2. The lower crew netting boat had to be repaired several times during Trip 9, 1993 due to failure of previous seam patching. This resulted in extra manpower to repair the boat on-site and loss of netting effort. The boat will be repaired and be in working order for the November trip.

## RECOMMENDATIONS

1. Further study into the Middle Granite Gorge aggregation of chubs should be implemented.
2. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report presents pertinent details associated with Trip 10, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 10, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 10, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 10, 1993. Table 4 is a summary of all humpback chubs marked or recaptured during Trip 10, 1993.

### Humpback Chubs Captured

A total of 754 humpback chub were captured during Trip 10, 1993 including 643 young-of-year (YOY) (<80 mm), 67 juveniles (80-199 mm TL), and 44 adults (>199 mm TL). Seven of these chub (all adults) were captured in nets in Reach 0. In Reach 1, 21 juveniles and 255 YOY were captured with seines. Three hundred and fifty-six chubs, including 10 juveniles and 246 YOY were captured electrofishing. Netting produced 37 adult humpback chub and 2 juveniles. One hundred and seventy-six chubs were also captured in unbaited minnow traps, including 34 juveniles and 142 YOY.

Of the 37 adult humpback chub captured in Reach 1, 31 (or 84%) were PIT-tagged recaptures (includes those captured and marked by other investigators). In Reach 0, three of the seven (43%) adults captured were PIT-tag recaptures. However, two of these fish were recaptures of fish tagged during the same trip. The third fish was originally tagged at RM 29.8 during Trip 3, 1993, approximately 0.5 miles from its original capture location.

Stomach contents of 10 humpback chubs were collected in Reach 1 using non-lethal stomach pumping techniques.

Two incidental mortalities of YOY humpback chub occurred during Trip 10, 1993. One YOY humpback chub was lost in a sein at RM 63.7 on October 17. The fish measured 58 mm TL. The second fish was found dead in the live well following an electrofishing run at RM 65.1 on October 17. The fish measured 44 mm TL. Both carcasses were preserved for transfer to AGF.

### Observed Condition of Humpback Chub

All chubs captured, with the exception of one juvenile appeared healthy and in good condition. The juvenile, captured in the vicinity of Lava Chuar, had a extremely malformed skull, most likely a

congenital abnormality. Except for the skull abnormality, the fish was in good condition. Also noteworthy were the presence of parasitic copepods (Lernaea sp.), on approximately 0.5% of juvenile chubs handled. It is suspected that these fish recently resided in the LCR where temperature regimes are more suitable for these parasites.

Non-lethal stomach pumping of 10 humpback chubs indicated that tapeworms were present in approximately 20% of the fish that were successfully evacuated.

#### Habitat Mapping

Juvenile habitat mapping was conducted in ten locations between the confluence of the LCR and Tanner Rapid.

#### Bench Marks

No new bench marks were established during Trip 10, 1993.

## **OBSERVATIONS**

1. Runoff from the Paria River created high main channel turbidity until October 14. Mainchannel turbidity above the LCR was low for approximately 1 day before another spate of turbidity created high turbidity above the LCR for the remainder of the trip. Turbidity below the LCR was high for the duration of Trip 10, 1993.
2. High densities of YOY humpback chub were observed in the main channel from the confluence of the LCR (RM 61.3) to Tanner Rapid (RM 68.5) during Trip 10, 1993. YOY humpback were captured in nearly all shoreline types by electrofishing, seining and minnow trapping.
3. All rainbow trout captured in conjunction with YOY humpback chub were sacrificed for stomach analysis. At least one trout appeared to have the remains of three unidentified fish in its stomach. These will be examined in the laboratory to confirm identification.

## **PROBLEMS ENCOUNTERED AND SOLUTIONS**

1. Copious amount of debris from the Paria, significantly affected netting efforts during the first day of Trip 10, 1993, resulting in reduced sampling effort.

## **RECOMMENDATIONS**

1. We recommend continued and enhanced coordination among the researchers in Grand Canyon. This coordination is essential to insure that all researchers are aware of others activities.

## INTRODUCTION

This report is the last of 36 trip reports scheduled to be submitted by BIO/WEST on this investigation. This report presents pertinent details associated with Trip 11, 1993. Included in the report are a summary of trip logistics, personnel and research schedule, data collected, problems encountered, pertinent observations and recommendations. Most information is presented in a tabular format to provide a quick synopsis of trip details and results. We emphasize that these data are hand tabulated to provide these synopses as soon as possible. The data are later computerized and checked for accuracy. The purpose of these trip reports is to provide information from BIO/WEST trips as quickly as possible to aid other researchers.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for Trip 11, 1993. Table 2 is a list of personnel who were present or participated in research activities for Trip 11, 1993.

## DATA COLLECTED

Table 3 is a summary of gear types used, sampling effort and fish captured by gear type for Trip 11, 1993. Table 4 is a summary of all humpback chubs marked or recaptured during Trip 11, 1993.

### Humpback Chubs Captured

A total of 270 humpback chub were captured during Trip 11, 1993 including 226 young-of-year (YOY) (<80 mm), 5 juveniles (80-199 mm TL), and 39 adults (>199 mm TL). Four of these chub (all adults) were captured in nets in Reach 0. In Reach 1, 1 juvenile and 21 YOY were captured with seines. Fifty-four chubs, including 5 adults, 2 juveniles and 47 YOY were captured electrofishing. Netting produced 25 adult humpback chub. One hundred-and-sixty chubs were captured in unbaited minnow traps, including 2 juveniles and 158 YOY.

Five adult humpback chubs were captured with nets in Reach 2. Two were captured in the Shinumo Creek area and three were captured in the Middle Granite Gorge.

In Reach 0, two of four (50%) adults captured were PIT-tag recaptures. Both recaptured fish were originally tagged at the same location of capture (a spring along the mainstem at RM 30.5) -- one had been tagged in April 1993, and the other in October 1993. Of 30 adult humpback chub captured in Reach 1, 23 (or 77%) were PIT-tagged recaptures (includes those captured and marked by other investigators). Three of five chub captured in Reach 2 were recaptures (60%). Two chub recaptured at RM 108.3 were previously tagged by BIO/WEST in July 1991 at the same capture location. One chub recaptured at RM 127.1 was originally tagged in November 1992 at RM 127.5, and was recaptured again in March 1993 at the same location. All recaptured fish in Reach 2 had grown in both length and weight since being tagged.

Stomach contents of 22 humpback chubs, 20 from Reach 1 and two from Reach 2, were collected using the non-lethal stomach pumping technique. All fish were released in good condition.

One incidental mortality of a humpback chub occurred during Trip 11, 1993. The YOY chub (47-mm TL) was discovered dead in a minnow trap on November 9 at RM 61.4. The bucket containing the specimen to be preserved was inadvertently emptied into the river and the specimen was lost.

#### Observed Condition of Humpback Chub

All chubs captured appeared healthy and in good condition, although parasitic copepods (Lernaea sp.) were noted on several subadult chub handled. It is suspected that these fish recently resided in the LCR where temperature regimes are more suitable for these parasites.

Non-lethal stomach pumping of 22 humpback chubs indicated that tapeworms were present in approximately 15% of the fish that were successfully evacuated.

#### Habitat Mapping

Juvenile habitat mapping was conducted in five locations between the confluence of the LCR and Tanner Rapid.

#### Bench Marks

No new bench marks were established during Trip 11, 1993. All benchmarks in Reach 2 were photographed for future use and documentation.

## OBSERVATIONS

1. Mainstem water turbidity was very low (Secchi readings of 1.0 to 3.4 m) from November 3 - 13. Excessive rain from November 11 - 15 increased turbidity levels, however Secchi readings never dropped below 0.4 m. The LCR was running and clear and low during the duration of sampling in Reach 1.
2. Observed densities of YOY humpback chub in the mainstem were considerably lower than in the previous several months. Extremely low seining catch rates in November (compared with high catch rates during high turbidity conditions in October) suggest that subadult humpback chub move into deeper, less accessible habitat with increasing water clarity. Minnow trap catch rates appear to correlate positively with water clarity -- this may be due to accessibility to deeper water habitat by traps (compared with seining) and/or greater utilization of cover (i.e., traps) by humpback chub under clear water conditions. Small numbers of subadult chub were captured fairly consistently from the LCR to Hance Rapid. No juvenile or YOY chub were captured in Reach 2.
3. Recapture rate for flannelmouth suckers in Reach 2 during this trip was 42 percent.
4. Approximately ten potential predators (including rainbow trout, brown trout, and channel catfish) were sacrificed for stomach analysis. Predation on humpback chub was confirmed for at least one predator -- the stomach of a brown trout (Total length = 495 mm; Weight = 1,514 g) collected at RM 65.15 contained one juvenile humpback chub (Total length  $\approx$  160 mm). The prey item had not been previously PIT-tagged. All other stomach samples will be examined in the laboratory for detailed analysis.

## PROBLEMS ENCOUNTERED AND SOLUTIONS

1. An electrofishing boat on the upper crew was inoperative for the entire day of November 11 -- after a lengthy search, a short was discovered in the anode boom and repaired. Excessive rain prevented complete electrofishing coverage around Lava Chuar and Papago Creek study areas.
2. The netting boat on the lower crew had to be repaired due to failure of previous seam patching. This resulted in extra manpower required to repair the boat on-site and loss of netting effort.
3. On the upper crew, two outboard motors were running rough and had to be replaced with spares. The faulty motors will be repaired in the shop.
4. One outboard motor was damaged while running Horn Creek Rapid. It was replaced immediately with no loss of sample effort.

## RECOMMENDATIONS

1. A program to monitor humpback chub during interim flows should be implemented in 1994. The large number of young chubs of the 1993 year class provides an opportunity to follow success of a large cohort through interim dam operations. If year class strength is a cyclic phenomenon, another opportunity to track such a cohort may not present itself for several years or more.
2. Continued study into the Middle Granite Gorge and 30-Mile aggregations of chub should be included in future research and monitoring efforts.
3. Food habits and food availability data collection should be incorporated into future research and monitoring for the 30-Mile, LCR, and Middle Granite Gorge chub assemblages.

## INTRODUCTION

This supplemental report was submitted to the Bureau of Reclamation by BIO/WEST, Inc., in partial fulfillment of a modification of Reclamation Contract No. 0-CS-40-09110, entitled Characterization of the Life History and Ecology of the Humpback Chub (*Gila cypha*) in the Grand Canyon. This modification was made to extend data collection, associated with specific elements of the life history and ecology of humpback chub in Grand Canyon, into 1994. One 18-day trip, during July 12 - 29, was conducted during 1994 for this investigation. This report summarizes the logistics, personnel, research schedule, results and recommendations from this supplemental investigation.

New findings made during this supplemental investigation will be integrated into the Final Report for work conducted during 1990-1993. Results related to specific objectives of this supplemental investigation are also summarized in this report and related to previous findings where applicable.

## OBJECTIVES

This supplemental investigation was conducted in the mainstem Colorado River by BIO/WEST, concurrent with Arizona Game and Fish (AGF) mainstem studies. Objectives of this supplemental investigation reflect specific emphasis on canyon areas and life history aspects of humpback chub. The objectives of the supplemental investigation were to:

1. Assess distribution, abundance, growth, habitat use and survival of the 1993 HB cohort in the mainstem below the LCR.
  - a. Collect additional information on sympatric native and non-native species with young HB in the mainstem below the LCR.
  - b. Assess predation of young HB by non-native predators in the LCR area.
2. Evaluate food habits of adult HB longitudinally through Grand Canyon.
  - a. Assess longitudinal incidence of Asian tapeworm in adult HB in mainstem.
3. Collect additional information on life history and ecology of the 30-mile and Middle Granite Gorge HB aggregations.
  - a. Refine density estimates of 30-mile and Middle Granite Gorge aggregations.
  - b. Evaluate HB spawning in the 30-mile area.
  - c. Map and characterize water quality of tepid springs in the 30-mile area.
  - d. Quantify adult HB habitat in 30-mile and Middle Granite Gorge area.
  - e. Refine information on distribution of adult HB in 30-mile and Middle Granite Gorge areas.
  - f. Collect additional information on sympatric native and non-native species with adult HB in the 30-mile and Middle Granite Gorge Areas.

## LOGISTICS, RESEARCH SCHEDULE AND PERSONNEL

Table 1 presents a summary of logistics and the research schedule for the supplemental investigation during July, 1994. Table 2 presents personnel who were present or participated in research activities during the trip.

### DATA COLLECTED AND RESULTS

Table 3 presents a summary of gear types used, sampling effort and fish captured by gear type during the supplemental investigation in July, 1994. Appendix 1 is a summary of all humpback chubs handled during July, 1994.

#### Reach 0 - Fence Fault (30-Mile area)

**Fence Fault Springs Survey.** A total of 12 springs were identified in the Fence Fault and South Canyon areas between RM 30.3 and 31.8 (Figure 1). All springs, except Spring L (Vasey's Paradise), emanated from river level between the 10,000 and 15,000 cfs stage elevation. Other springs may have been present below this level but were not detected or observed. Most springs surfaced through fractures in Redwall limestone and were located in a 0.5 mile reach (RM 30.3 to 30.8) around Fence Fault. Only three springs at river level were located below this point.

Estimated discharge from springs ranged from less than 0.1 cfs (seeps) to 10 cfs (Table 4). Discharge of at least one spring (Spring H) varied with river stage. Temperatures of undiluted springs ranged from 21 to 21.5 °C with the exception of Spring L which was 17°C. Spring L (Vasey's Paradise) was located above river level, and possibly originated from a different groundwater source than other springs in the area. Differences in dissolved oxygen, pH, and conductivity measured in undiluted spring water from Spring G and Spring J also suggested different water sources for each side of the river. At Spring G, on river left, dissolved oxygen, pH, and, conductivity measured 4.36 mg/l, 6.34, and 2,230  $\mu$ mhos, respectively. Readings at Spring J, on river right were 6.0 mg/l, 7.24, and 353  $\mu$ mhos, respectively.

Configuration and area of thermal plumes associated with individual springs varied depending on morphology of the river channel at the spring source and magnitude of discharge from the spring. Springs A - G and K entered the river along fast eddies and runs. High current velocities and turbulence at the mouths of these springs resulted in rapid dilution of tepid spring water. Thermal plumes were characterized by a narrow band of warm water extending downstream and compressed against the shoreline. In contrast, Springs H, I and J entered the mainstem in slow eddies or runs. Thermal plumes of these springs tended to be larger and remained relatively stable, at flow fluctuations observed during the trip (10,000 to 15,000 cfs).

Physical characteristics of Spring J were examined in detail during July 1994. Thermal characteristics and configuration of the plume were measured and hand mapped at mainstem flows of approximately 15,000 cfs (Figure 2). Temperature at the spring's source was 21.5°C. Plume temperature was approximately 15°C, 2 m from the source, 12°C, at 3 m from the source and was not perceptibly different than the mainstem at 10 m from the source. Approximate area of the plume was 3 m wide and 10 m long. The mouth of the spring was located in a limestone shelf along the shoreline. Substrates in the plume were composed of bedrock limestone, boulders and sand.

**Distribution and Abundance of Humpback Chub.** A total of 19 humpback chubs, including 5 adults and 14 YOY were captured in the Fence Fault area. All adults and YOY were captured at one location (RM 30.7), near the confluence of a Spring J (Figure 1). During previous BIO/WEST sampling efforts in the Fence Fault area, approximately 69% (18 of 26) humpback chubs have been captured from this same location. Larval light traps were also used during July 1994 in an attempt to capture larval fish in and around springs near Fence Fault. Traps were fished over-night in calm water near the confluence of springs where possible or downstream of spring areas in calm waters of eddies or embayments. No larval fish were captured.

Two PIT tagged adult humpback chubs, marked on previous BIO/WEST sampling efforts in the area, were recaptured in July 1994, resulting in a recapture rate of 40%. One fish was originally captured on September 10, 1993 at RM 30.7 and the second on November 9, 1993 at RM 30.6. Population estimates of adult humpback chub in the 30-Mile aggregation were recalculated with the addition of data collect in July 1994. These computations resulted in a population of 37.6 fish, with a range of 20 to 120 fish. This number is slightly lower than the previous estimate of 39.8 fish as of November, 1993.

**Humpback Chub Spawning.** Three of the five adult humpback chubs captured in Reach 0 during July 1994 were lightly tubercled. Of these, one was a male expressing milt, and one was a female described as 'spent' based on abrasions on the ventral surface, swelling around the vent, and a flaccid abdomen. It was estimated that the female had spawned approximately two to four weeks prior to capture based on healing of abrasions and appearance of the vent area. Other humpback chubs exhibiting signs of spawning readiness have been captured near springs on previous BIO/WEST sampling trips, including one ripe male in May of 1993, and three tubercled adults (two males and one female) in September of 1993.

Approximately 100 YOY humpback chubs were observed in the mouth of the spring at RM 30.7 on July 14 (Photo 1). Fourteen fish were captured using an aquarium dip net to verify identification. These fish ranged in size from 18 mm to 31 mm total length (TL), with an average length of 24 mm. Three additional visits were made to the spring to observe the location of the fish in the plume. During each visit a temperature was taken at the location where the fish were observed. Temperatures utilized by the YOY humpback chub ranged from 16 to 19°C. The fish were consistently observed utilizing cover provided by boulders and sparse overhanging vegetation within 1.5 m from the source of the spring.

Standard length (SL) of YOY humpback chub captured at RM 30.7 was derived using the formula:

$$SL = TL * 0.822$$

Average standard length for the 14 fish captured was computed to be 20 mm. From this, it was estimated that these fish were approximately 36 days old, or hatched on June 8, 1994, based on the growth curve developed by Muth (1990) for humpback chub cultured from brood stock from the LCR at temperatures of 18 - 23°C:

$$Y = 7.2843e^{0.0280X}, \text{ where } Y = SL, \text{ and } X = \text{days after hatching}$$

The equation was written as follows to solve for X:

$$X = \frac{\ln Y - \ln 7.2843}{0.0280}$$

The presence of numerous small YOY humpback chub and the capture of a recently spent female provided strong evidence that humpback chub utilized Spring J for spawning during 1994. Approximately 2 to 3 m<sup>2</sup> of the thermal plume consistently maintained temperatures greater than 15°C, suitable for spawning and egg development. Substrates in this area were primarily bedrock limestone. Several limestone boulders and small amount of sand were also present. Crevices and interstitial spaces between boulders would have provided egg deposition areas with some protection against predators such as carp, which were frequently observed in the mouth of the spring during night time sampling. Sand was the prevalent substrate in areas of the plume away from the mouth of the spring.

The concentrated use of Spring J by of humpback chub appears to be a unique phenomena in the Fence Fault area. Netting and electrofishing adjacent to other springs in the area indicated only sporadic use by humpback chub. A large slow eddy on river right, approximately 0.5 miles downstream of Spring J, is the only other location in the area where humpback chubs have consistently been captured. No springs were found in the eddy during surveys in July, but existence of spring sources below river level cannot be ruled out without more exhaustive surveys. High catch rates of gravid and ripe rainbow trout and carp, adjacent to other springs in the area, indicated that these fish may also utilize springs as spawning habitat. Large numbers of ripe male and gravid female trout were captured in the mouth of Spring A during March 1993. Carp have been consistently captured in the vicinity of Springs J and H, including several ripe males.

#### **Reach 1 - LCR Confluence to Red Creek.**

**Humpback Chub Captured.** A total of 267 humpback chub were captured in between RM 60.0 and RM 76.5 including 34 adults, 79 juveniles and 154 YOY. Adult humpback chubs were captured in trammel nets between RM 60.0 and RM 65.4 for purposes of food habits studies. Sampling of adults was discontinued when sufficient numbers had been captured. Two juveniles were also captured in trammel nets. One hundred seventy three humpback chubs were captured electrofishing including 71 juveniles and 102 YOY. A total of 58 humpback chubs were captured in minnow traps including six juveniles and 52 YOY.

**1993 Humpback Chub Cohort.** A primary objective of sampling in July 1994 was to assess the distribution, abundance, growth and survival of the 1993 year class of humpback chub in Reach 1 of the mainstem Colorado River. Intensive electrofishing and minnow trapping between RM 61.3 and RM 76.5 was conducted to address this objective. Seining was also used initially, but was discontinued because of its ineffectiveness in clear water conditions in the mainstem during July.

Longitudinal distribution of subadult humpback chub between the LCR (RM 61.3) and Red Creek (RM 76.5) appeared to change little between the last three months of 1993 and July, 1994. Longitudinal catch rates for electrofishing and minnow trapping indicated that subadult humpback chub were distributed throughout the study reach during July 1994 (Figure 3). A similar breadth of distribution was also observed during September through November of 1993. Of interest however, was the large amount of longitudinal variation in catch rates during each sampling effort in 1993 compared to a relatively uniform catch rates during July 1994. This suggested that dispersal of young

humpback chub into the mainstem Colorado River during 1993 initially resulted in a "clumpy" distribution pattern that evened out substantially prior to July 1994.

Consistently lower longitudinal catch rates during July, 1994 compared to September through November of 1993, indicated that densities of subadult humpback chub had declined in the study reach. This was particularly evident in certain specific areas, such as RM 68. Comparison of pooled catch rates in the mainstem Colorado River from the LCR (RM 61.30) to Lava Canyon (RM 65.4) also indicated densities of humpback chub decreased during the same period (Table 5). Pooled electrofishing catch rates decreased 74.2% between September, 1993 and July 1994, while pooled minnow trapping catch rates decreased 71.5% for the same period.

Growth of the 1993 year class of humpback chub could not be detected from length-frequency data collected in Reach 1 (Figure 4). Lengths of subadult humpback chub captured during July, 1994, ranged from 18 to 195 mm TL, with an average of 63 mm. Similar length distributions were also seen in September through November, 1993. Shifts in the distribution to larger size class, that would have signified growth, were not apparent. It is likely that significant overlap in length distributions between cohorts reduced the effectiveness of length-based growth analysis. Differences in growth rates between the LCR and mainstem Colorado River, protracted spawning periods, and variation in timing of immigration of young humpback into the mainchannel are factors which may contribute to an overlap of sizes between year classes. Other techniques for distinguishing cohorts and estimating growth are currently being assessed and will be presented in the Final Report for BIO/WEST humpback chub studies.

## **Reach 2 - Middle Granite Gorge**

**Distribution and Abundance of Humpback Chub.** A total of 14 humpback were captured in the Middle Granite Gorge area (Reach 2) including 10 adults and 4 juveniles. All adults were captured in trammel nets between RM 127.0 and RM 127.5. The four juveniles were captured between RM 125.8 and RM 127.5, two by electrofishing and two in minnow traps. All humpback chub captured in July 1993 were within the range established for the Middle Granite Gorge aggregation during previous BIO/WEST sampling from 1990 to 1993.

Population estimates of adult humpback chub in the Middle Granite Gorge aggregation were recalculated with the addition of data collect in July 1994. These computations resulted in a population of 108.3 fish, with a range of 76.0 to 155.9 fish. This estimate was slightly higher than the previous estimate of 103.9 fish as of November, 1993.

## **Longitudinal Food Habits Study - Humpback Chub**

A total of 39 humpback chub were stomach-pumped for food habits analysis during July 1994. The technique was successful on 31 of 39 fish, resulting in either evacuation of the stomach contents or a determination that the stomach was empty (Table 6). The eight unsuccessful attempts were related to blockages of the fish's gastrointestinal tract that prevented the typical flushing action of the pump. This block may have been associated with large amounts of algae or other coarse materials that could not be flushed from the fishes gut without excessive pressure. Macroinvertebrates and algal drift were collected concurrent with stomach pumping efforts to assess availability of food items in the drift. Four sampling location were used for both drift sampling and stomach analysis (Table 7).

**Drift.** Invertebrate relative abundance in drift samples was dominated by Chironomidae at all four sites (Table 7). At Site 1, Annelid worms, included in other aquatics represented 45% of the drift (numbers of organisms). Simuliid relative abundance tended to increase in a downstream direction, from 8% at Site 2 to over 20% at Site 4. Relative abundance of Gammarus lacustris increased from slightly from 1.56% at Site 1 to 2.51% and 2.97% at Sites 2 and 3, respectively, then declined to 0.27% at Site 4. The low value at Site 1 was unusual given its proximity to Gammarus production below Glen Canyon Dam, relative to Sites 2 and 3.

**Stomach Contents.** The small sample size (N=1) of humpback chub gut contents successfully sampled from Site 1 (30-Mile area) limited analysis of food habits in this area of the canyon. Stomach contents of the fish that was successfully pumped was composed of 4 ml of Cladophora and four Chironomids. Partial gut contents retrieved from one other humpback chub at Site 1 included three Annelids. This was the only occurrence of Annelids in humpback chub gut contents from the July sample.

Simuliids were found in 19 of 22 (86.4%) humpback chub gut contents and represented the most commonly utilized food item at three sites within the study area, followed by Chironomids and Gammarus (Table 8)(Figure 5). Longitudinal trends in occurrence of food items suggested that Gammarus, Chironomids and Cladophora were utilized less in Middle Granite Gorge (Site 4) than around the LCR (Sites 3 and 4). Occurrence of other aquatic and terrestrial invertebrates exhibited no apparent longitudinal trends. Terrestrial food items in Grand Canyon may be primarily associated with tributary flooding, making their availability seasonal and ephemeral in nature. Little tributary flooding was observed during the July sampling trip.

Simuliids were the most prevalent invertebrate in the humpback chub diet, comprising an average of 34.6% of the volume of gut contents (Table 9). This taxa appeared to be particularly important in the Middle Granite Gorge area, where it occupied 88% of gut content volumes of six fish. Gammarus comprised an average of 13.1% of gut content volumes, and represented the second most prevalent invertebrate food item. Highest volumes of Gammarus were observed from the two sites near the LCR, and dropped substantially at the Middle Granite Gorge site. Volume of chironomids and other aquatic and terrestrial invertebrates were very small at all sampling sites. The occurrence of a small whiptail lizard (Cnemidophorus sp.) in the gut of one humpback chub from Middle Granite Gorge was not included in volumetric analysis. Volume of this lizard would have substantially increased the volume of terrestrial food items at the site. Cladophora comprised a relatively large portion of gut content volumes at the 30-Mile and LCR sampling sites, but was not found in gut contents from Middle Granite Gorge.

Numerically, Simuliids were the most abundant organism found in humpback chub stomachs followed by Chironomids and Gammarus (Table 10). Pupal and larval forms of Simuliids were much more prevalent than adult forms in humpback chub stomachs.

Food habits data collected during July 1994 indicated that Simuliids were the dominant food item for humpback chub in most areas of Grand Canyon. A limited sample from the 30-Mile aggregation indicated that Cladophora may be an important food item higher in the Canyon. Gammarus also appeared to be an important food item for humpback chub in the LCR area. Although Chironomids were the most abundant invertebrate found in the drift, utilization by humpback chub was relatively low. The apparent selectivity for Simuliids relative to their abundance in the drift indicated that

humpback chub do not rely on drifting food items for the bulk of their diet. It appears that either Simuliid behavior predisposes them to predation by humpback chub or they are actively sought for their energetic value. Blinn et al. (1992) reported that Simuliids have the highest energy value, 22.64 joules/mg dry wt., of common aquatic food items in Grand Canyon. It is interesting that Chironomids, which have the second highest energy value at 21.38 joules/mg dry wt., were apparently not selected by humpback chub. Further investigations into food habits of humpback chub and the life history of prey items may provide valuable insight into their foraging behavior.

**Incidence of Asian Tapeworm.** Asian tapeworms were found in stomach contents of 3 of 30 fish (10%) successfully stomach pumped (Table 11). Only humpback chub captured in Reach 1, below the LCR (RM 61.3) were infested with tapeworms. Three of 12 (25%) humpback chubs successfully pumped in this reach had tapeworms in the gut contents. Infestations ranged from 1 tapeworm in each of two fish and a minimum of 15 tapeworms in the third fish.

Stomachs of 10 fathead minnows were also examined for tapeworm in Reach 1 below the LCR. A tapeworm was found in one of the 10 fish, indicating a infestation rate of 10% for this species.

## SUMMARY OF FINDINGS

1. Twelve springs with a wide range of discharges, physical characteristics, and water quality were identified in the Fence Fault area of Marble Canyon between RM 30.3 and 31.8. Sixty-nine percent (18 of 26) of all adult humpback chubs captured in the Fence Fault area have been captured in the vicinity of one of these springs, identified as Spring J.
2. Observations of 50 to 100 YOY humpback chubs in the mouth of Spring J, confirmed that humpback chubs successfully spawned in the thermal plume of the spring in 1994. Additional evidence was provided by the capture of a spent, adult female humpback chub in the vicinity of the spring during the trip.
3. Assuming that humpback chubs spawned in portions of the plumes where water temperatures were greater than 15°C, substrates used for spawning included limestone bedrock and limestones boulders ranging from 0.25 to 1.0 m in diameter. It is speculated that eggs were deposited in crevices in the bedrock or interstitial spaces around boulders to have survived predation by adult carp that frequented the spring outflow.
4. Distribution of subadult humpback chub (<200 mm) from the mouth of the LCR (RM 61.3) to Red Creek (RM 76.5) in July, 1994, was similar to distributions observed during September through November of 1993 and indicated that young humpback chub are utilizing suitable habitats throughout the reach.
5. Decreases in electrofishing and minnow trap catch rates from September 1993 to July 1994 suggest that densities of subadult humpback chub in Reach 1 below the LCR have decreased approximately 70%.
6. Growth of humpback chubs from the 1993 year-class could not be assessed due to the inability to distinguish cohorts from length-frequency data.
7. Food habits data collected during July 1994 indicated some longitudinal variation in diet of humpback chub in Grand Canyon, with Cladophora and Gammarus utilized more frequently by fish in the 30-Mile and LCR areas. Volumetrically and numerically, Simuliids were the dominant item in humpback chub gut contents at all sites except the 30-Mile area, where they were not found.
8. Asian tapeworm was found in 3 of 30 humpback chub stomachs contents examined during July, 1994. The three chubs infested with tapeworm were captured in Reach 1, below the confluence of the LCR, suggesting a possible link between the life cycle of the parasite and the LCR.
9. Asian tapeworm was found in 10% (1 of 10) of fathead minnow stomachs examined.

## RECOMMENDATIONS

1. Spawning of humpback chub in Reach 0, from the confluence of the Paria (RM 1.0) to Kwagunt Rapid (RM 56.0) should continue to be evaluated. Emphasis should be placed on spring sources around faulted areas such as Fence Fault and Eminence Break.
2. A more complete water quality analysis, including gaseous nitrogen, of springs in the Fence Fault area should be conducted. This information could provide insight into why humpback chub and other fish species appear to exhibit preference for specific springs in the area.
3. The incidence of Asian tapeworm in humpback chub and other suitable host species in Grand Canyon should continue to be evaluated. Understanding the life history and ecology of this parasite and its affects on humpback chub populations may have implications in the future management of aquatic ecosystems of the mainstem Colorado River and its tributaries in Grand Canyon.
4. Techniques for marking subadult humpback chub, less than 150 mm, should be evaluated as a research item. Marking fish would enhance the ability of researchers to evaluate growth and movement of early life stages of humpback chub in Grand Canyon.

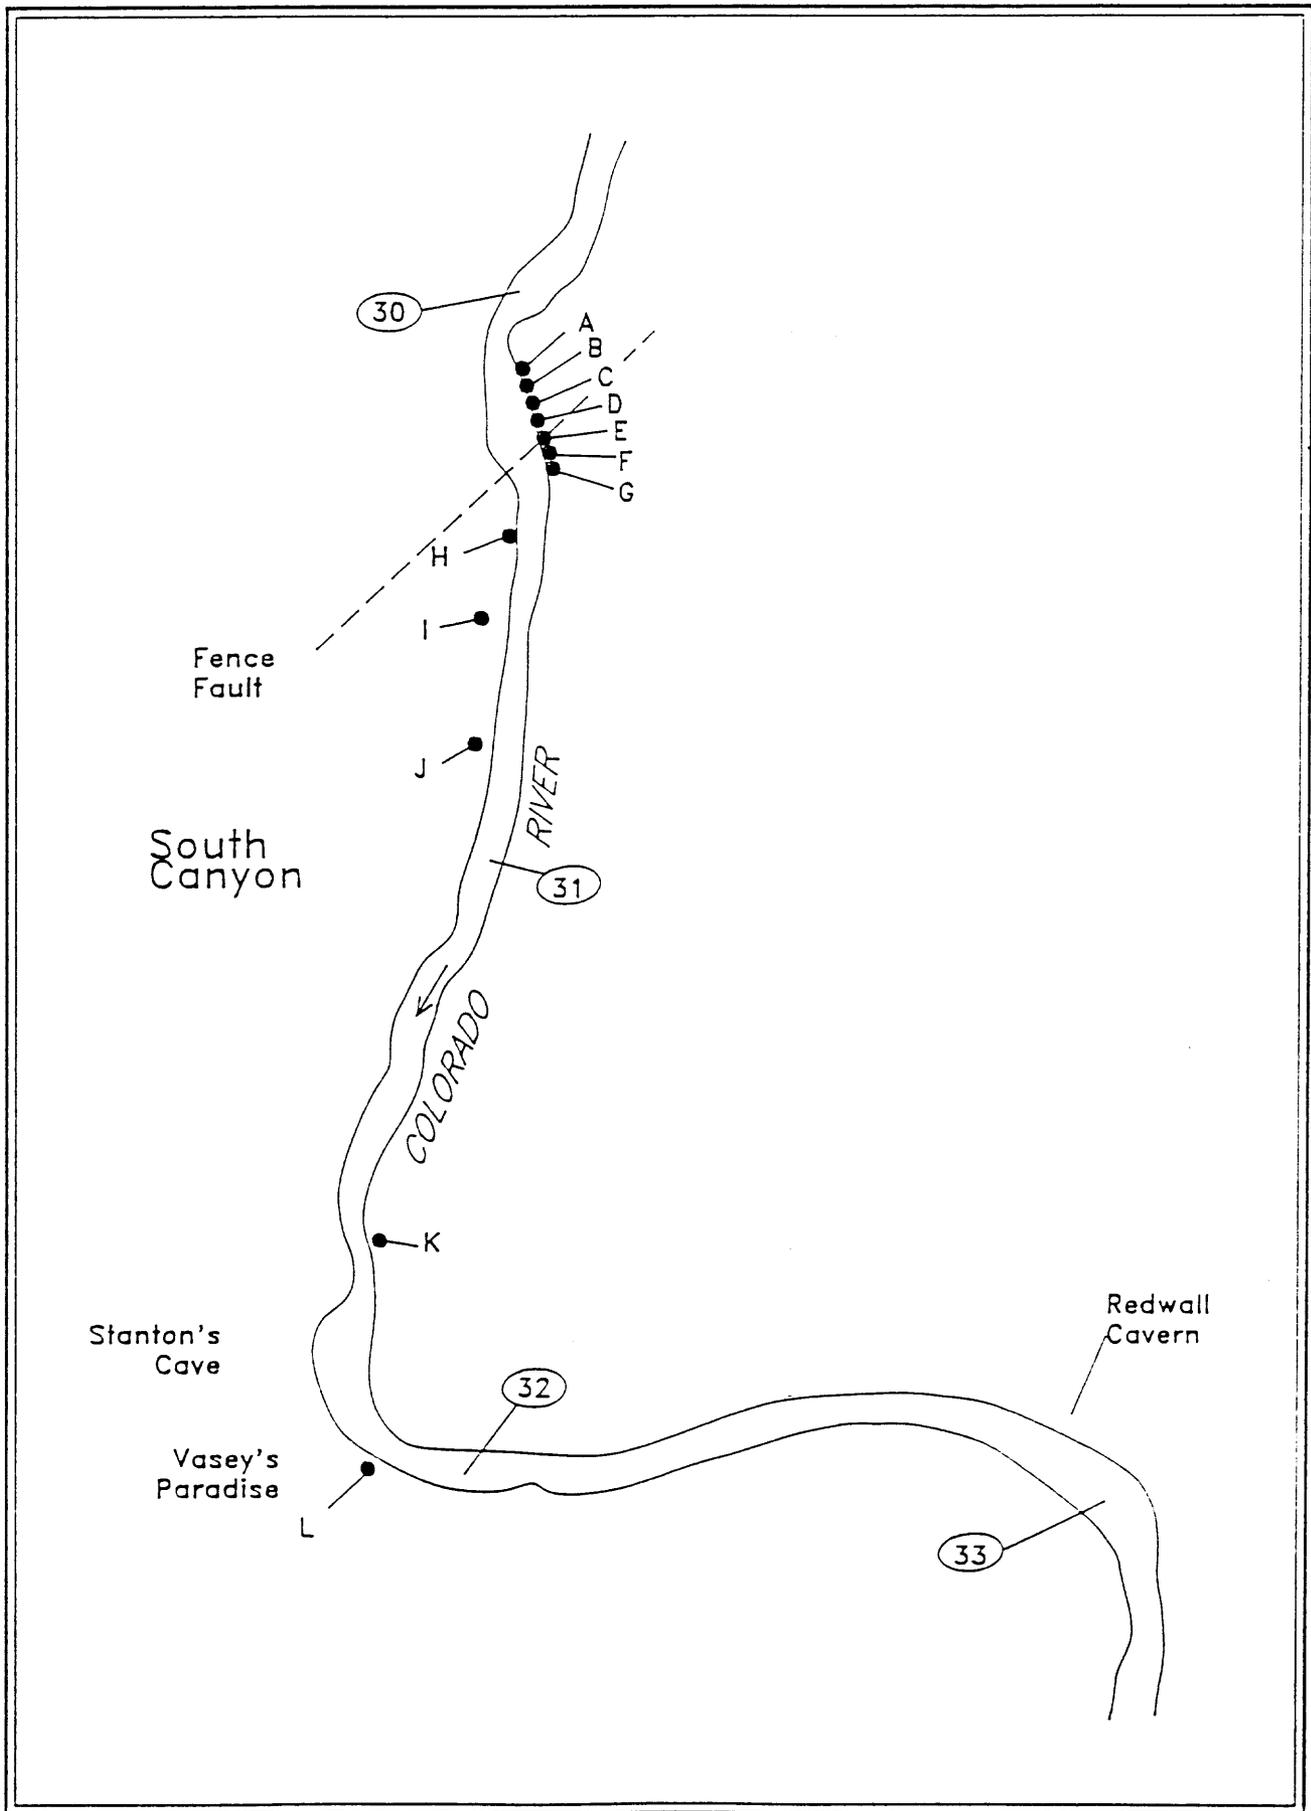

Figure 1. Locations of 12 springs (A-L) in the Fence Fault Area.

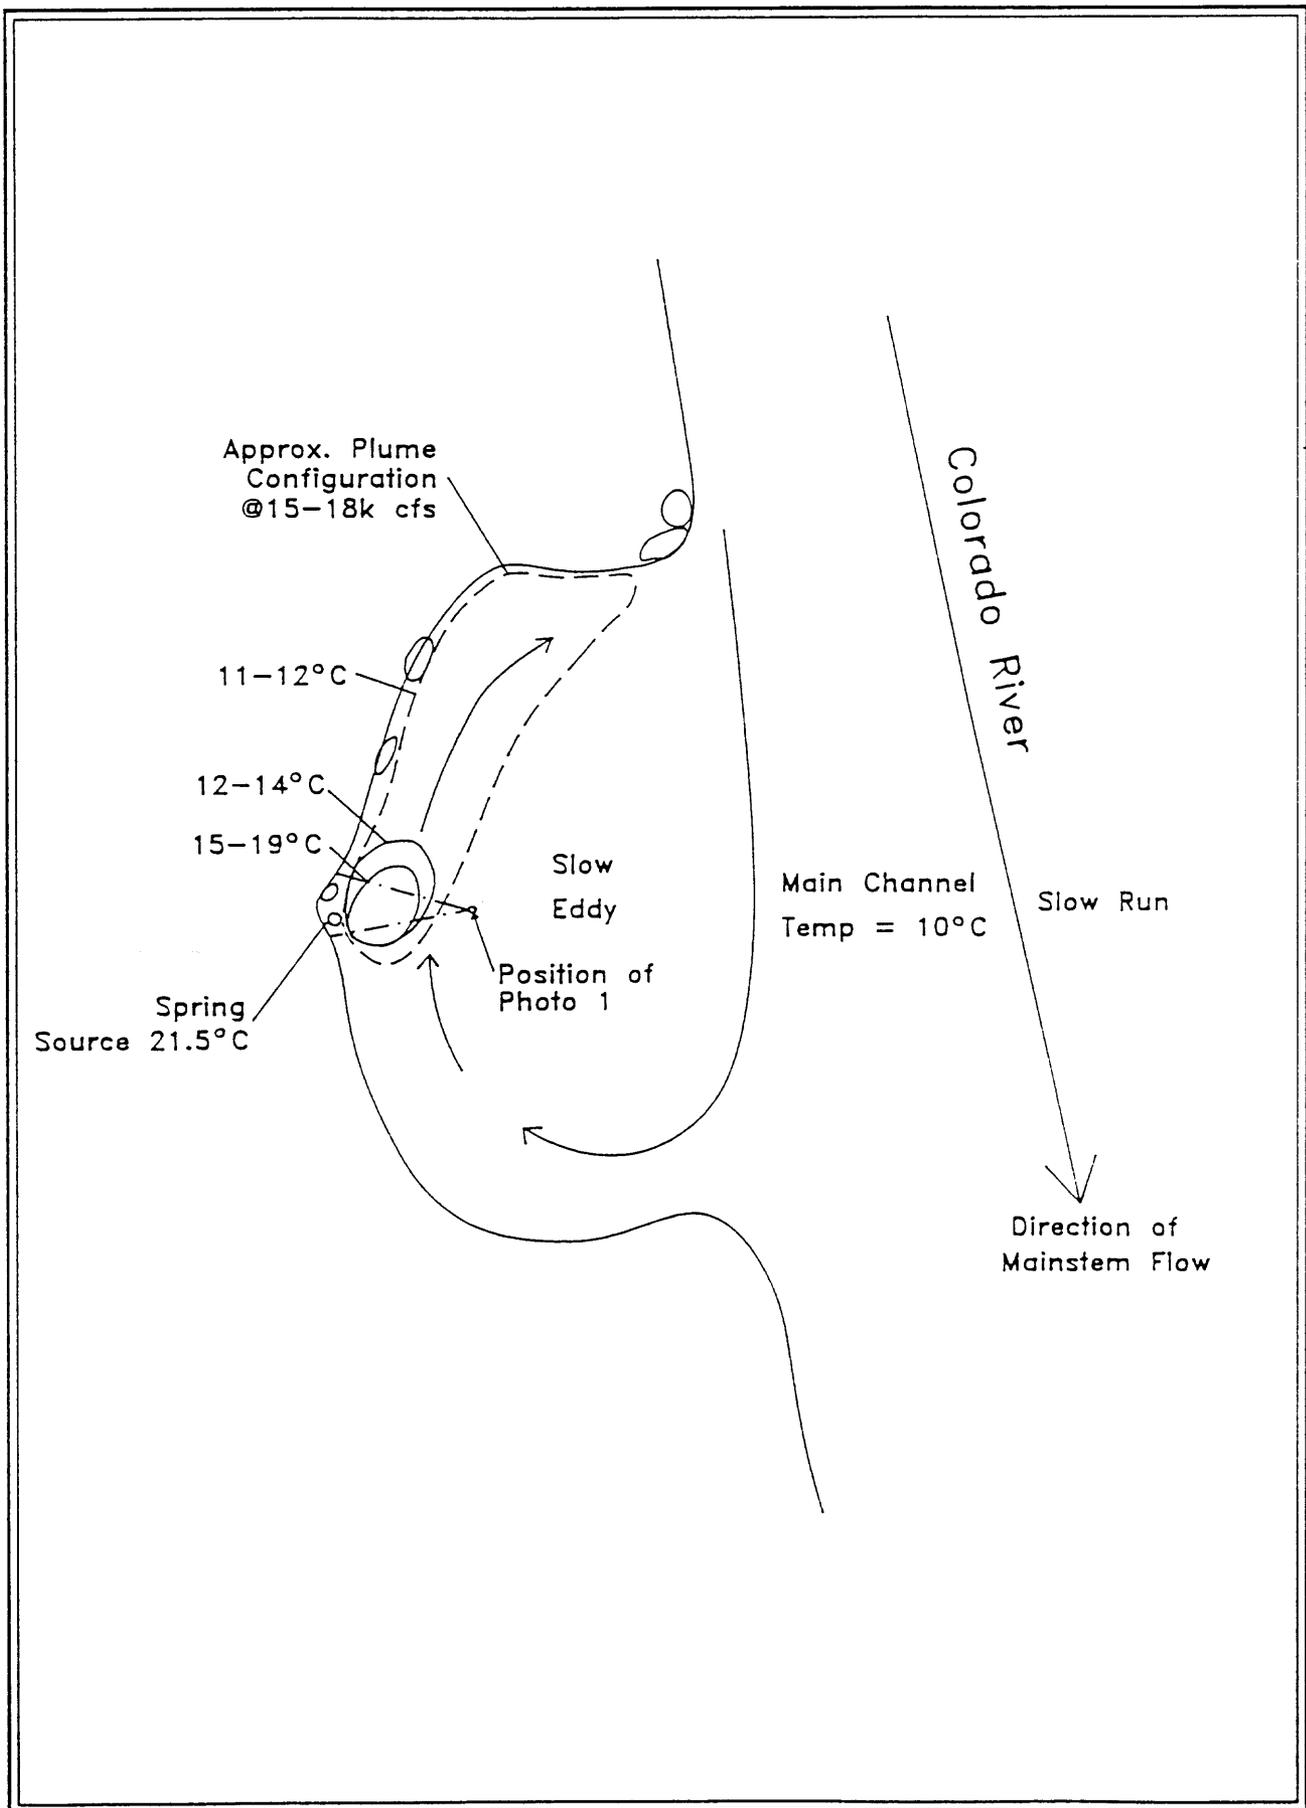

Figure 2. Approximate plume shape and thermal characteristics of Spring J at RM 30.8. Data collected July 14, 1994, with a Hydrolab Surveyor 3.

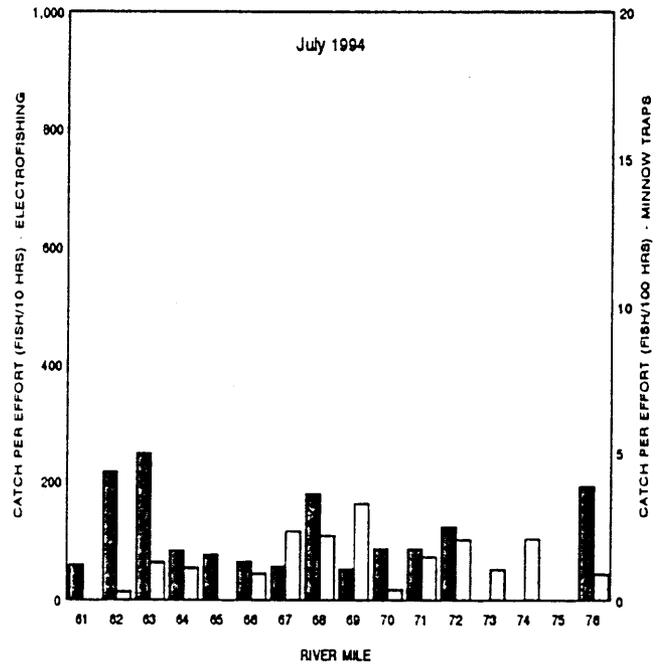

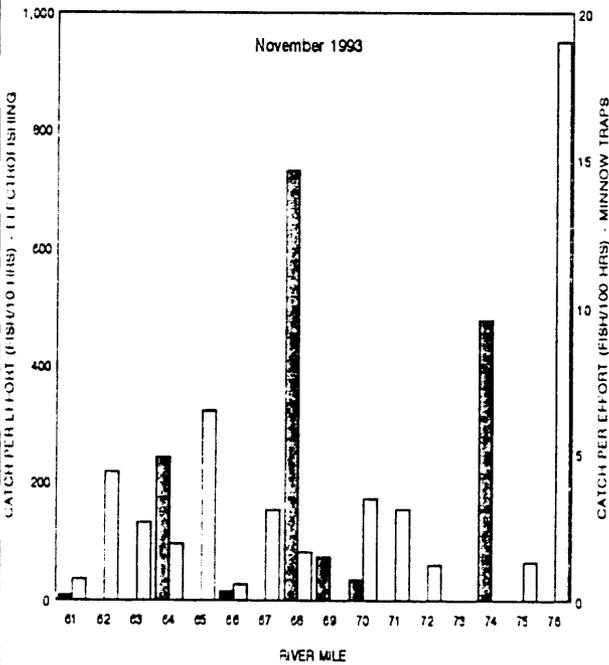

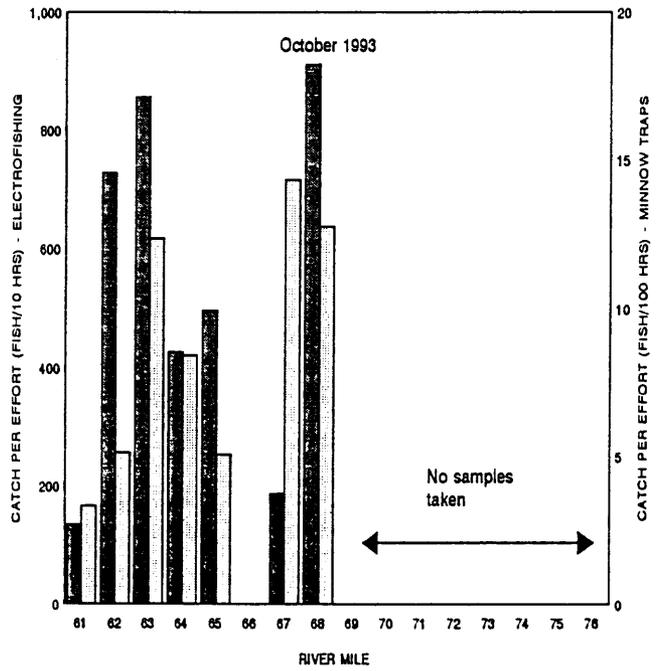

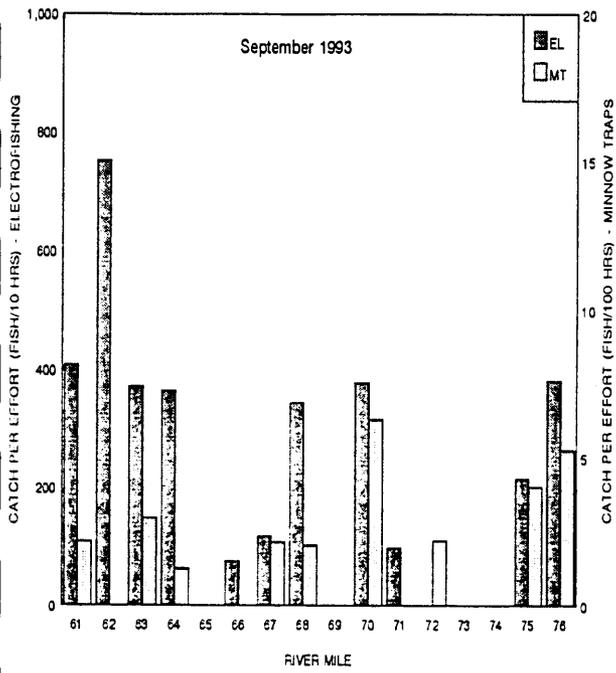

Figure 3. Longitudinal electrofishing and minnow trap catch rates (arithmetic mean CPE) by mile for Reach 1, below the confluence of the LCR, RM 61.3 to RM 76.5, for September through November 1993 and July 1994, in Grand Canyon, AZ.

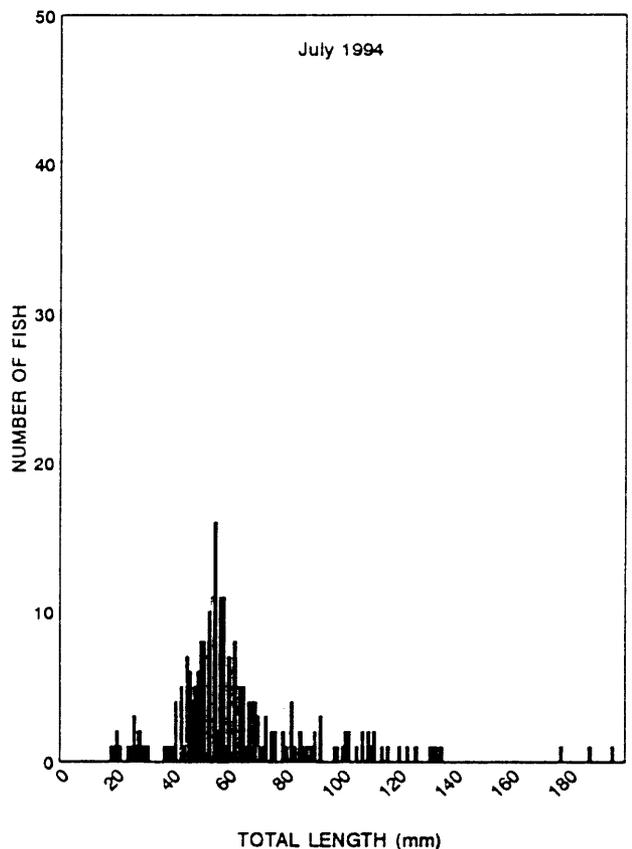

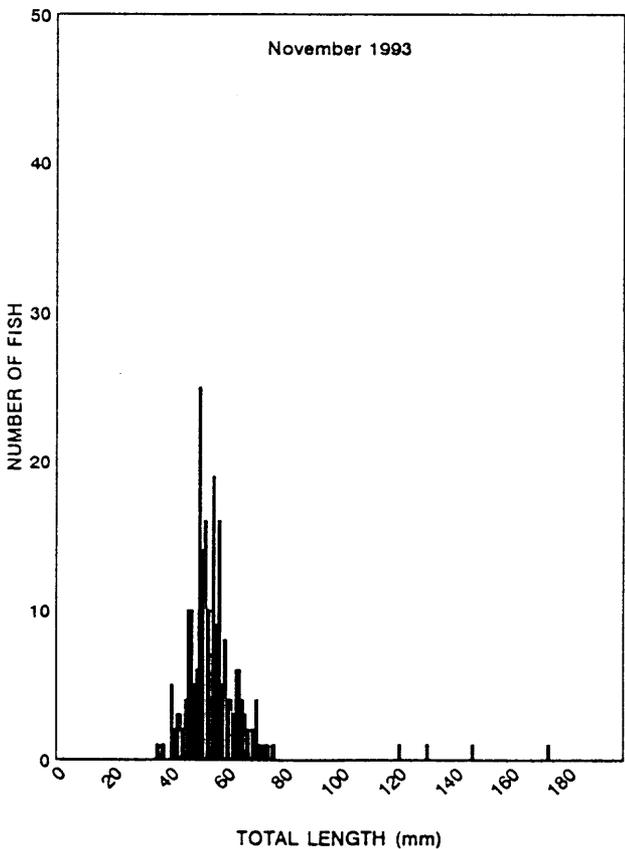

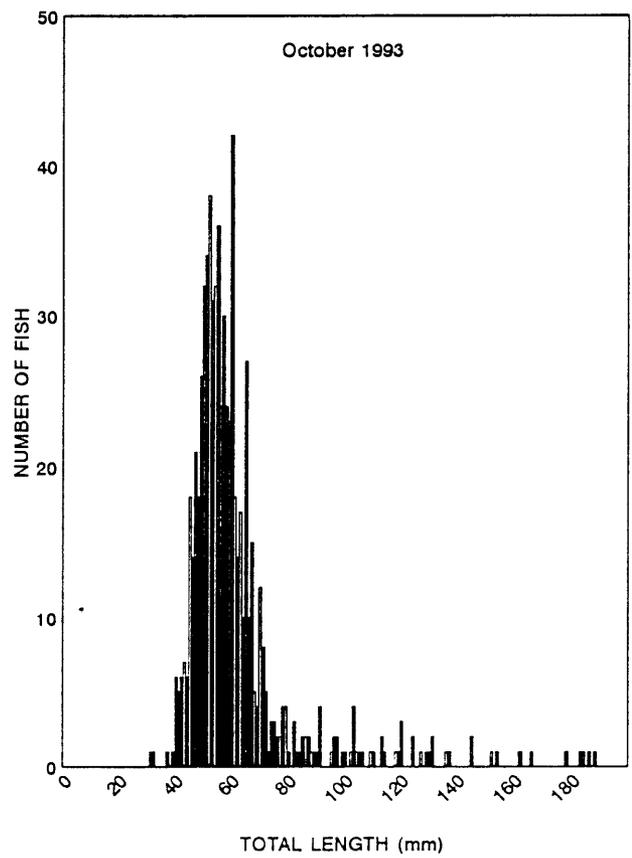

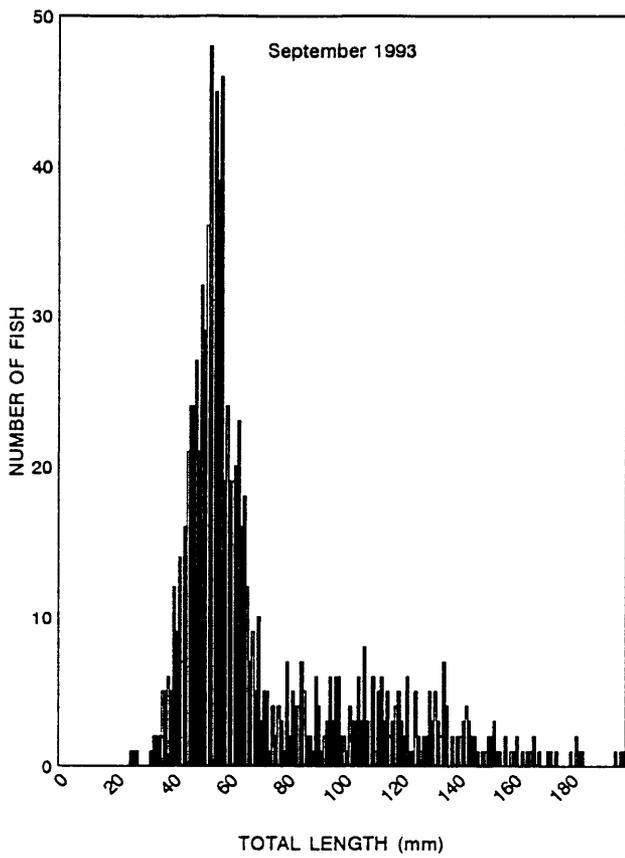

Figure 4. Length frequency histograms, by 1 mm increments for humpback chub captured in Reach 1, below the LCR, RM 61.3 to RM 76.5, for September through November 1993 and July 1994, in Grand Canyon, AZ.

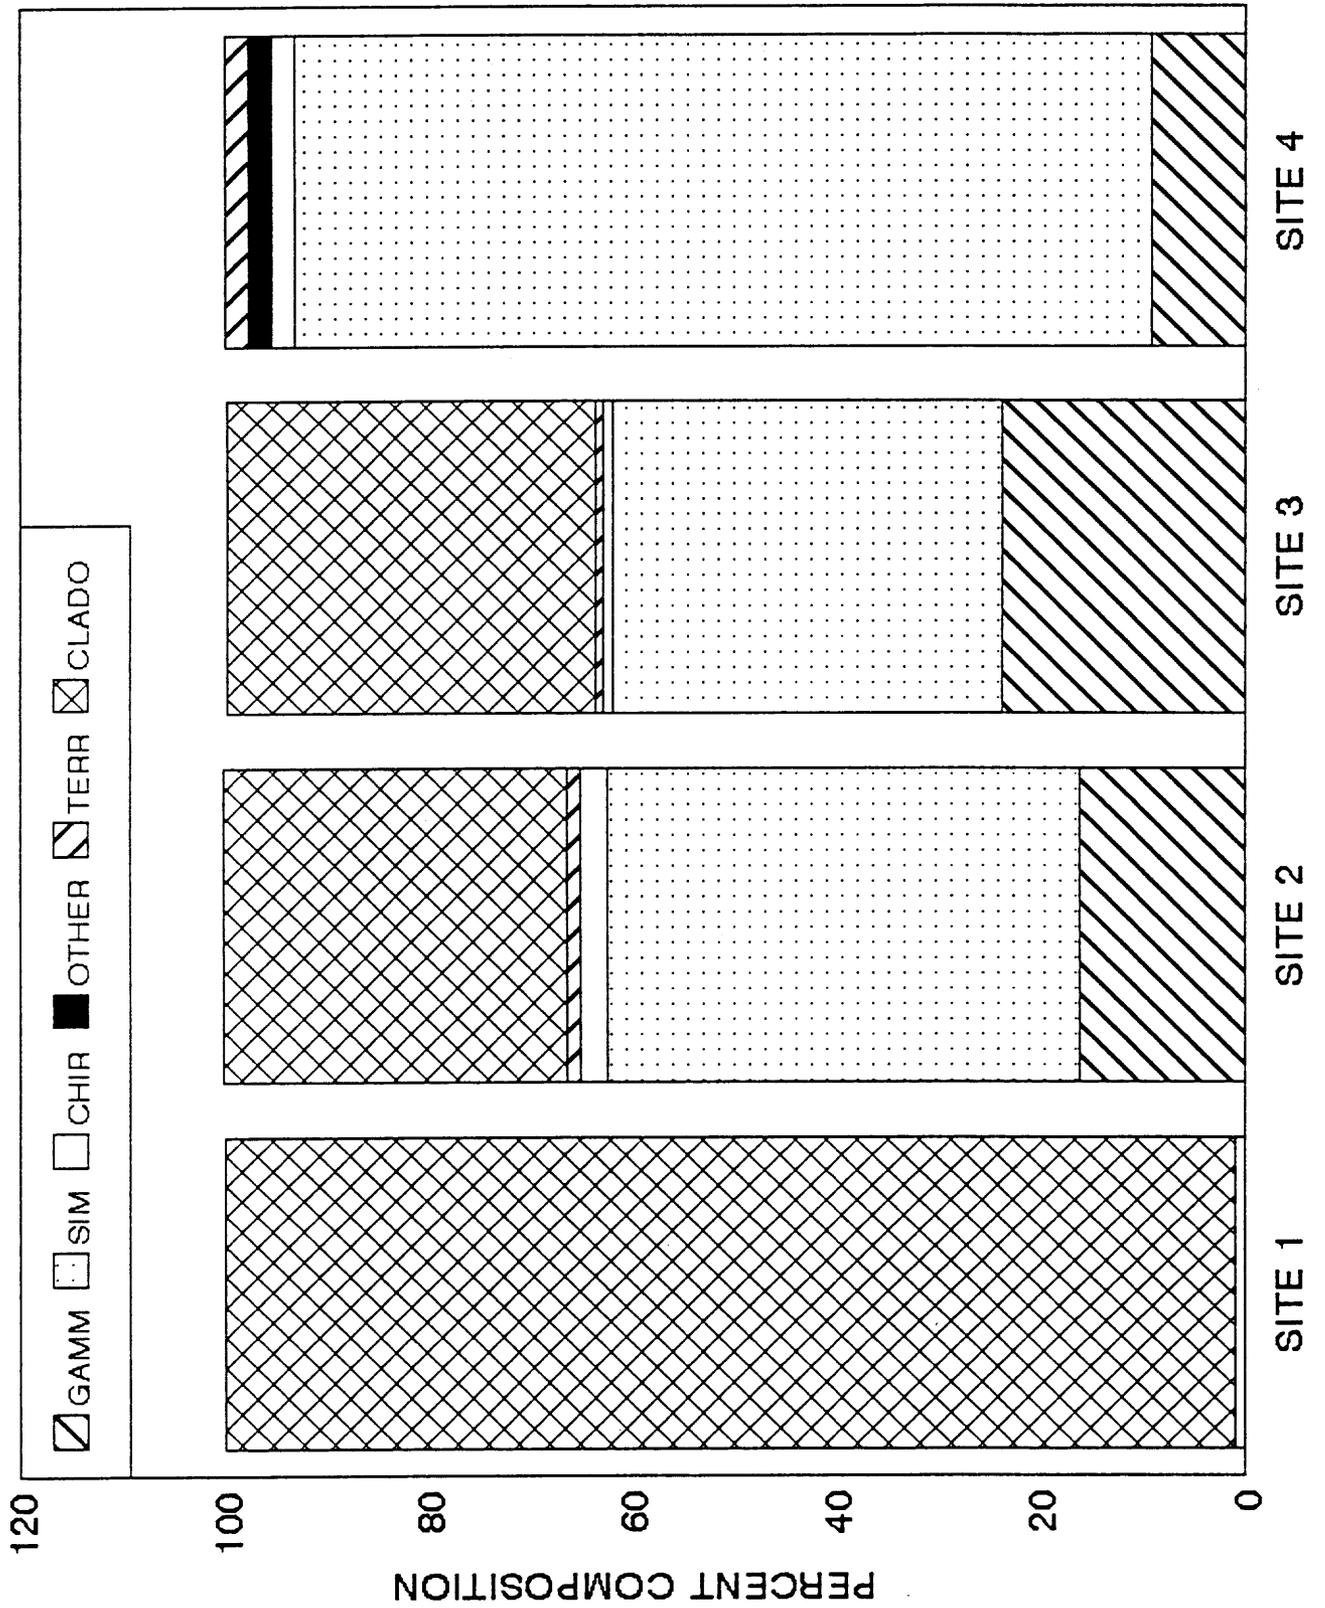

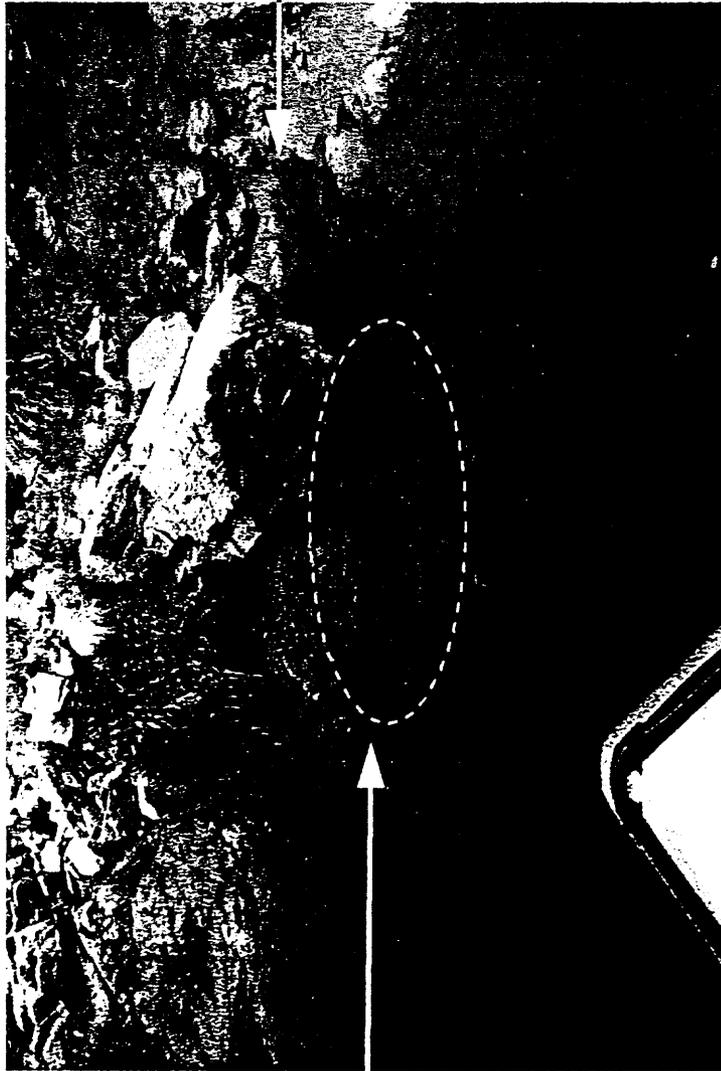

Figure 5. Percent composition of volume of food items found in 22 humpback chub at four sites during July 1984 in Grand Canyon. Site 1, N=1; Site 2, N=8; Site 3, N=7; Site 4, N=6.

Humpback Chub

Spring  
source

Photo 1. Photograph of Spring J at RM 30.7, Grand Canyon. Approximately 100 YOY humpback chub were observed in the mouth of the spring at the time of the photograph on July 14, 1994. See Figure 2 for location and angle of this photo.
